Teflon RG-303 is 0.170" in diameter.

Yep, it is possible I did, won't be the first time. The orginal
question stated that the swr was somehow measured at the source, how
else could one know it was 1:1. The measurement instrument was not
specified. Assume that it is the average ham with a 50 ohm swr bridge,
an antenna analyzer, and a 50 ohm RLB. If one changes to 1/2 wave 72
ohm cable, using the same measurement instrument you get the same
results.
I understand the mechanics of the actual VSWR on mismatched lines,
but I intrepreted the the question differently I guess. My handy Smith
Chart program reports a 1:1 VSWR, of course it is only at the source,
at 90 degrees it reports 2:1. Wonder what that program uses to
calculate swr?

I'd also add, a 5 watt cb rig, at that close range, could damage the
706. I'd just shut each rig off while the other is transmitting.

By the way, curious, but what does Honda charge for a factory
installed cb setup?

Dear Mr. Richard Clark:
Amen. You understand. Without structured and documented programming one has trash (I know a few other descriptive words that would be applicable). One of my students and I once built an automated EMC measuring system that was under computer control. With the use of documented and structured programming, changing instruments or the DUT was straight forward. Furthermore, since each module was "rung-out" the reliability did not suffer when things were changed. (Just to bring a bit of EMC related subject matter into the discussion.) I am sure that many reading this site know the pain of working on software that is not structured.
Thank you for your effort and skill in making the critical points clear.

My first boss had a boss, the mistake was made in putting him UNDER a real bureaucratic MBA... every friday, no later than monday morning a complete printout of our project had to be on this @$%@#$%'s desk--it was COBOL!!!

I am sure he packed it home, showed it to his neighbors, impressed his wife, children and friends with it--possibly even laid in on the bar while knocking back a few, and the bar patrons were appropriately impressed...

... anyway, he NEVER did figure out, the code was always the same, always years old and from another project... but being about 4 inches thick, it must surely have intimidated him to look...

... another thing he may NEVER have noticed, my boss would put little rhymes and stories in the comments (and constantly change these)--he was a pretty good writer and jokester, and many were funny--perhaps he only asked for the printout so he could read those... <grin>

Warmest regards,
John

Thanks Dave, I'm using 450 ohm ladder line and some triming brought
the SWR down to about 1:8 to 1.

73 Gary.

Thanks for the information. I am using 450 ohm ladder line. Some
trimming as Cecil recommended brought it down to about 1:8 to one.

Thanks for the info John. I'm really surprised that assembler is still used. Like I mentioned my experience was limited to an 8 bit 6502 processor and I suspected assembler was probably a goner by now.

I'll never forget the days of trying to decipher some TRS-80 Model 1
Basic. You might read the first line or two and then have to a "goto
10000" statement for some subroutine. Spaghetti it was !

I've heard it said that there's more lines of Cobol in use than all the
lines of all the other languages combined.
That's not too surprising though, considering the wordiness of the language.
IBM mainframes and the AS400 both still use COBOL - (and another one you
didn't mention - RPG).

mine is pretty close to a true quad. cut for 80m. fed with 450 ladder line to a tuner. i like it. it gets kinda touchy on the higher bands. but for 80 and 40, it's the best thing i have ever used. lowest corner is about 15 to 20 foot off the ground. highest is about 45.

i agree, put it up and go with it. you'll soon learn which direction it "hears" the best.

Hi,

This is a hypothetical question, if one needs to send more power down a line than its capacity can 2 or more lines be paralleled? Is the equivalent characteristic impedance of the combined lines the same as that of a single individual line?

A*s*i*m*o*v

... The bird of paradise alights only upon the hand that does not grasp.

> Teflon RG-303 is 0.170" in diameter.

Yup, .023" smaller than standard RG58. That, plus the slick Teflon
jacket may well allow him to pull up two Teflon cables in place of his
RG58.

If the CB is off, you are likely not to have problems. If it is on,
it is possible. I don't know how likely, tho, as the quality of the
front end may make all the difference.

Hi Brett,

You are talking about deCSS which proved irrevocably that NOT
following structured routes leads to ruin.

>After some super team of "structured
>programmers" and "goto-less coders" sold the movie industry the idea it
>was safe to release their product in digital form? Un-breakable
>encryption they claimed--wasn't it?

Once again, you supply a pale argument that literally exposes the
opposite of your bias. Those who "sold" this idea were NOT code
designers. You might carry more weight if you researched your
material before littering it here.

As Bruce Schneier offers in "Applied Cryptography," rolling your own
security is the easiest form of protection to crack. Clearly this
group who spun together CSS never got past his chapter 2 "Protocol
Building Blocks" and, if you haven't gotten the message yet, is
clearly the highest statement of structured programming around. Did
your college offer this subject as a weekend reading assignment during
Chico homecoming?

>Hey, aren't you from that industry--or did I get that wrong? <grin>

I doubt you could name an industry I haven't worked in. I also dug
ditches with the SeaBees and ran with many Diesel Boat Sailors. They
would unanimously qualify your BS as rather lame. I suppose most of
this has become tediously boring for others, why don't you try your
hand at antennas where foolish statements have at least an even field
for others to meet you on?

The short answer is no to the question of the impedence being the same.
though the current would be halfed in each line. I'm not sure that I have
see a four wire open line in the past but if my memory is correct it fed
two dipoles not one.

Let's say we parallel two pieces of lossless 50 ohm coax such
that the voltages at the load (V1 and V2) are equal magnitude
and phase. The currents at the load (I1 and I2) will be equal
magnitude and phase.

For matched line operation, V1/I1 = V2/I2 = 50 ohms.
Pload = (V1*I1)+(V2*I2) = 2*(V1*I1)
Vload = V1 = V2
Iload = I1 + I2
Rload *for matched line operation* = V1/(I1+I2) = V1/(2*I1).
Rload = 1/2(V1/I1) = 50/2 = 25 ohms. So 25 ohms is the
equivalent Z0 of two pieces of 50 ohm coax in *parallel*.

Conversely, if you use one piece of 50 ohm coax going to the
load and one piece of 50 ohm coax coming back from the load
to achieve a shielded balanced feedline, the Z0 of that
feedline is 2*Z0 = 100 ohms and the two lines are in *series*.

An interesting article on such is "Quadro-Line: The Ideal
UHF Transmission Line", ARRL Antenna Compendium, Vol. 3.
It's four box-spaced wires in a parallel type transmission
line. Two adjacent wires have a Z0 of 200 ohms. Paralleling
the four wires yields a Z0 of 100 ohms. Choosing two diagonal
wires yields a Z0 of 250 ohms.

John, I have difficulty, and probably do others, in understanding your poetry.

Can I respectfully suggest you restrict your language to plain American-English and avoid Old English Shakespeare as beautiful and amusing as it may be.

Richard would also do better at communicating his ideas if he continued along the same lines. I'm sure there's lots of sense embedded in what you both have to say. But I am unable to dig it out.

Now please carry on with what you were saying.

Incidentally, I've now switched to South African red wine. And I'm not on speaking terms with my doctor. By chance he is a radio amateur who uses a G5RV. His nurses have more common sense.

Reg.

Richard:

The "180 phase-shift" in our thinking, I referred to, relates to this:

You mental-model knowledge as a well of water, if too many men drink and use--it may run dry.

My model is upon a virtual well, one of the mind, the more men (and women) who drink strengthen the source which feeds this well--and the "water of knowledge" springs forth in abundance. Indeed, it should only dry up if men obfuscate even the location of this well with quotes from Shakespeare! (Or worse, movies!)

Another example:
You model newsgroups as a few experts imparting their wisdom to the ignorant masses....

I model the newsgroups as a place where ignorant men overcome their limitations by group effort...

And, another:

You model antenna hobbyists as SUPERSTARS, each going to make enormous contributions on a solely individual basis...

I view us as a more socialistic model--where no man is of any significance and the results of the whole is what matters...

... and that appraisal/opinion of mine is what prompted me to state what I have and prompted me to the "180 phase-shift conclusion"...

Warmest regards,
Brett AKA John

Hi Brett,

None of it makes sense simply because you speak of life like an old
man waiting to die. If you wish to characterize my mode as "playing a
game," you should note that your indictment describes me as having
more vitality than your circular and repetitive excuses for embracing
a morbid ethic.

(Sorry Reg if too much of this English is derived from the Normans -
is this something Americans can cope with that Brits still fume over
after a thousand years? You know, you write very little authentic
Anglo Saxon in the first place to protest. Even more, those Mead
drinkers would sneer at your continental foppery over wine.)

So, we are all well acquainted that you will not yield a point without
deflections of tepid japery - give us your best rebound.

Indeed, these are certainly legacy languages. It might, however, ruffle a few feathers to throw COBOL into the same basket as Pascal. Your local bank manager or technical advisor may disagree violently on this subject.

That is, even if we ignore the fact that Pascal was primarily created to be a teaching language and Fortran was always a niche language (where it did quite well, and still does), there's quite a bit of life in COBOL yet.

This is my understanding since being pulled kicking and screaming into mainframe development because our customers demanded support of iSeries and z/OS environments. I can say with all honesty that it is possible to learn enough COBOL to make a small TCP/IP app that works quite well in busy mainframe environment. So far the bugs I'm finding are in Java on Win32 :)

In the process of doing so I also learned that not only is there more COBOL code being actively maintained than any other language, out of all new enterprise "mission critical" software development projects last year COBOL was the language of choice for over 50% Of all new application starts, COBOL represents 15% See <http://www.csis.ul.ie/cobol/Course/COBOLIntro.htm> (I have no affiliation with this site, nor have I independently verified these numbers which appear to originate from the Gartner Group.)

I'd expect the former, given how many legacy apps written for hardened banking, medical and insurance systems are written in COBOL. I mean, Gartner reports that there are 240 billion lines of maintained COBOL out there. All other languages represent 60 billion. That's a lot of COBOL code.

The last was a surprise to me. I imagine numbers like this can be sliced any way you like, but in my short experience there is a lot of active COBOL development going on out there.

A lot of this has to do with the fact that the ANSI/ISO standard for COBOL has been constantly updated, while allowing 40-year old apps to still compile and run.

COBOL is easy to make fun of, but it still casts a deep shadow; I suspect it will continue to do so for years.

This happens regularly. There are all kinds of neat languages to look
at. One of the tenets of "Pragmatic Programming" is to learn a new
language a year if you are a working coder.

My favourite new (to me) languages lately are Ruby and Haskell. The
former is a pure Smalltalk-like OO interpretive language. Great
prototyping language. The latter is a very pure functional language.
For those of us who cut our teeth on functional languages, it's quite a
fresh look.

He'd be breaking the letter of the law but -- assuming he dialed the 706 back to 5W -- not really the intent, IMO. I really can't imagine the FCC pursuing the issue. True story: I used to live next door to a guy with a linear amp on his CB, I called up the FCC field office, and they told me there wasn't anything they could do. Said they had official monitoring stations that, if they picked up the guy's transmission, they could go after him, but they just didn't have the resources to pursue complaints from people calling in violators. And, oh, did I want their free brochure on mitigating interference to my own electronics?

:-(

I bet a Goldwing CB is also closer to $1k than $150!

It may be a truism that COBOL coders are older than other coders (I'm in my 30s) and that these people /may/ be driving the decisions to continue to use it. I don't agree this is the primary driving factor for how COBOL gets used in the real world.

That fact is that a good number of huge corporations (often referred to as the "Global 1000") continue to use COBOL regardless of the age of their project managers. COBOL has outlived the first wave of original users of the language. Apparently the mean age for a working mainframe developer is in the 35-45 demographic. These guys were just babies (like me!) in 1968. Someone mentioned that last year's SHARE conference had a younger crowd than ever before. There is talk about a "third-wave" of mainframe developers (a demographic I'm not in a hurry to join.)

Like I said, we have over 40 years of very, very mission critical systems to maintain. These corps are very, very conservative about changing these systems. It is naive, at best, to think that there is one single factor that would drive these corporations to switch to something else the day they retire the last old-timer.

I'm personally glad that banks, insurance underwriters and telcos use big iron running truly time-tested technology to keep their uptimes measured in years.

I not suggesting that COBOL will never be replaced. I'm suggesting that things will not "crumble" but will be slowly migrated in a *highly* controlled manner to other systems. Generally, this means that legacy systems continue to work just as they always did, with features and add-ons coming in the form of frameworks like MQSeries from IBM.

At any rate, I'm not sure we can trust anyone's crystal ball. All we know is that traditionally the shops that use COBOL do not like risk of any sort, and love to manage risk as much as possible. Any move away from COBOL will be steady and controlled, and will likely keep people employed for years to come.

For this reason alone, COBOL belongs in another pile altogether from Pascal or even FORTRAN.

In fact, this very reasoning supports some of the decisions that the embedded world makes. There are less and less reasons to make hand-coded assembler or use speciality languages like real-time C or Forth. Not unless one happens to be in the embedded systems world, whereupon it suddenly makes a whole lot of sense. When you are making 1000 widgets that will be deployed for decades and then promptly forgotten about, it makes sense to consider "alternatives" to the status quo.

Is there a reason for anyone who doesn't work on z/OS or iSeries to learn COBOL? No. Does the fact that small application shops, shops that target home and office PCs and hobbyists don't use a language make that language obsolete? Absolutely not.

The thing I've learned about this business is that one never know as much as one thinks they do!

Depends on how you read the FCC's intent. If the intent is to limit
power output on the band, yes. If the intent is to require that all
CB transmitters be specifically certificated for this band, no.

The FCC's letters and findings (e.g. when they bust a dealer for
selling "10-meter amateur radio" systems easily converted to 11-meter
operation) seem to me to be asserting the latter pretty consistently.

> I really can't imagine the FCC pursuing

>didn't have the resources to pursue complaints from people calling in
>violators.

They do seem to be fairly limited in their ability (or motivation) to
pursue such violations. There are quite a few places on the Net which
advertise "10-meter" radios and also offer "11-meter conversion"
services for 'em. I think I can count, on the fingers of one hand,
the number of dealerships which have been cited for such things in the
past couple of years, and I'd probably have one or two fingers left
over.

> And, oh, did I want their free brochure on mitigating interference
>to my own electronics?

I seem to recall that somebody (FCC, Congress, ??) pushed through a
change to the laws/regulations, and explicitly gave local
law-enforcement organizations the legal power to prosecute cases of
interference caused by illegally-amplified CB transmitters. Most
police departments are likely either to not know this or not be
terribly interested in pursuing such cases, but in case of severe
unrelenting interference from a known point of origin it might be
worth trying to get them to act on it (on "creating a public nuisance"
or similar grounds).

As to the OP's query - in his situation I'd be tempted to try to wire
up a set of RF and DC relays, which would prevent both rigs from being
powered up at the same time, and would short the antenna connection on
the unpowered rig.

clvrmnky:

As I have already stated, I have given up religious wars over syntax... all that is left for me is to wonder why anyone would go on developing in it (COBOL--I understand maintaining old code for economic reasons)

All which stands clear to me is that "C++" can do all of what the others might achieve, combined (barring assembly, which is the root of all)...

... if MBA's dream of reading source and understanding it--not even COBOL will grant them their dream... though they might pretend, more or less successfully...

If you do not trust your programmers, you will limit them with their language--I guess I am luckily I still have a position where all which matters is our results and the department head is a strong programmer with acceptable backbone... the coding dept here is looked upon as a blackbox, you hand us specs, we give you working code... if all goes well, no complaints... no one second guess you...

I know COBOL programmers argue syntax as if their very lives depended on it (other languages too, to at least a degree), why has always been a complete mystery to me, in the end I just chalked it up to fear of "C"...

To try to give you a perspective of how this looks to me, the guy with cobol looks like he is standing there with a sliderule in hand--the "C" programmer as having a graphing scientific calculator in hand... both can get the job done--I just expect to obtain better results from one...

Warmest regards,
John

Christopher:

Excuse my humor in my previous post.

Roger beeps are considered VERY bad behavior when used on ham bands.
Indeed, the only place I have ever seen them used is by truck drivers on
the CB band.

They shortly grow annoying... I would suggest against their use, but if
you really have to have one, ask on rec.radio.cb they will be able to
provide you with a source, I am sure...

Warmest regards,
John

For 60hz power lines there's no problem, and impedence isn't usually an
issue,
but since we're on an antenna group, we assume you're referring to RF
transmission line.
If you parallel 2 lines - the overall impedence halves
If you run 2 lines in series (which <looks like> parallel) its like having
twinlead made from coax - and the impedence is doubled.
I've used combinations of both for making matching sections.

Hal

It surprises me to read that you consider the Smith Chart difficult to
use. I'd bet that you could figure out how to use one to your benefit
within 20 minutes of asking questions of someone who uses them.

Jerry

Jerry,
You're probably right. I could probably lean how in an afternoon.
I sat down with one I printed out once, and thought I had it figured out.
Then when I needed to use it again, I would need to be retrained.
I remember how to use an MFJ259 from use to use, though. :-)

I just don't have the patience - it just doesn't grab my attention like a
gizmo does.

So now you're pickin' on my slide rule? Is nothing sacred??
I like my slide rule. Its more useful than my solar-powered flashlight.
The slide rule works without <any> power or batteries. :-)
And its accurate to 3 (sometimes 4) significant digits.

The term "old slide rule" is a bit redundant, some would say.
My new slide rule is only about 30 yrs old. Plenty of life left in it.

My Motorola Maxtrak beeps just as I key it to talk on the 800 mhz
band. Does that qualify as a roger-bleep? It should be built into your
Motorola, too.

Just what kind of a bleep are you looking for? Talk about picky :-(

Roger beeps are actually used a lot on VHF SSB here in EU,
and they nicely show what an inefficient mode SSB is. Hardly
a VHF contest goes by, when I do NOT hear a station in SSB
calling me, where everything I can clearly copy is the
rogerbeep ;)

The cost of a CB intigrated system radio on a Honda Goldwing is around $900 US and it's made by Panisonic. As for the FCC nabbing a motorcyclist for operating his amateur radio on CB, well even if they could track him it's not worth the effort. AKA how many truckers are using a lot more than 5 watts and you don't see many of them being targetted by the FCC. I know because I used my 706 on 11 meters when my Cobra went up in smoke on me on a trip to Arizona. And would you believe the state tropper in the Port of entry scale was more interested in my scanner than anything else. And then only till he found out I was a licenced amateur, then he wasn't interested at all. What he told me was that state law had no aurthority to do anything when it came to radios if I held an amateur radio licence. He said the last thing they want is the Feds breathing down on him for causing trouble to a licenced amateur radio operator, regardless if he's from Canada, USA or Mexico it's the same thing. But now watch yourself in the state of Washington, the FCC is hot and heavy in this state, I think it has a lot to do with the military bases on the Pacific Northwest.
I had my 706 on my old GL1200 and it worked like a charm, mind you I didn't run full power, a motorcyle battery is no where near as hefty as a car or truck battery and my head is a little too close to the antenna to suite me. You do know wher the term "hothead" came from.

A poor algorithm and bad math can be implemented anyway you like,
strutured or kludge and it will be broken. Of course, it will be
easier to see what went wrong with the structured code. A good crypto
system can be done by hand and be un-crackable or DES can be done as
elegantly as is humanly possible and we all know what became of DES.

Russ, who has probably written as much code as anyone out there

Hi Russ,

Schneier holds that only ONE cryptographic system is un-crackable: a one time pad - provided you (you meaning the pair in communication) have the only key and then destroy it immediately after ONE use. Every thing else succumbs to brute force if the secret's lifetime (its value over time) is long enough.

Basically it boils down to cycles/cent, and the CSS lobby made their algorithm the cheapest crack on the market. Roll your own security and that's the consequences. Ultimately, security is no better than the last bozo to touch the code.

Dan Brown's "The Digital Fortress" is a page-turner that moves on these very precepts. The classic by Clifford Stoll, "The Cuckoo's Egg" is an excellent detective story illustrating the perils in real (1980s era) life.

Solar powered flashlight? Heck, we have a made up loony lefty here in Minneapolis who wants people to use electric powered generators to reduce noise and pollution during emergencies. Morgan Q. E. Wolfe-Slattery, a true Euphorian.

I have 2 slide rules that I picked up recently, but I miss my easy on the eyes yellow aluminum Pickett LogLogDeciTrig (I think that's what it was) that got misplaced during a move a couple decades ago. I also wish I still had my HP35, 45 and 11C. I do have a working HP25, 15C and 48SX though.

Russ:

A good disassembler on a fast computer can rip through structured binary code at hundreds, maybe thousands of lines a minute in a best case scenario... generating readable assembly instructions which can easily be converted into any syntax you would like... (course you gotta start figuring out what "varible1" and "variable2" represent in the real world--teenagers seem gifted to this)

... get Intel's "Big Book" on the processor and learn to use the tricks to break this within the source code and disassembly ends up a mess... a really good in-house optimizing compiler can be used to obfuscate code a bit too... (production compilers which been "cracked" can actually be used to aid in the disassembly, telling exactly how they built the code)

...in the end, the more structured the better the disassembler can "guess" the code and spit out source a 15 year old teenager can eat up... sometimes there is little need to worry about such, and sometimes you just don't have a choice...

... then there are those who have never even heard of such things, one real user of all these tricks and more is M$ itself... IBM has been another... and if you really want to make your head spin, take a look at the compiler Intel sells--those boys know all the tricks... the compiler ain't cheap, and its code has NEVER been cracked (not fully understood in its operations)... been around for years, scarce due to the fact it holds the hackers at bay (they don't have a bunch of cracked copies they can use)... now Intel knows how to obfuscate!

... now is the time the pin head fairy dancers come out to play...

Warmest regards,
John

Source record: 76036

As others have said, yes, you can run two parallel lines. An easy way to think about the impedance: assume the lines are independent, and each has a matched load equal to Zo. Parallel them, and the load is Zo/2. Since a (uniform) line with matched load presents a Zo load to the source, the source with two such parallel lines will see a Zo/2 load.

BUT...BEWARE! What if the two lines are not equal electrical lengths? The results may surprise you. Details are left as an exercise for the reader. You can use standard transmission line equations, or use a program like RFSim99, to see what happens. Try, for example, a couple of lengths of lossless 100 ohm line with v.f. = .66, one of length = 100 feet and one of length = 101 feet. (I'm curious what others get for results...)

Cheers,
Tom

Hal

First off -- I realize that you are eperienced enough with antenna
analysis to know what is needed for matching them. And, if you did want to
use a Smith Chart, you'd have done it by now. I wont embarrass myself by
telling you anything I know about them. But, they sure can help identify
what kind of impedance is needed for a matching network.
Any impedance with a real resistive value can be plotted on the chart.
Then, its location immediately identifies what reactance will move the
unmatched impedance toward a matched location. I think you already knew
that. I also think you could teach me how to look at matching devices from
a more practical perspective.

Jerry

75. Handheld GMRS/FRS radio antenna gain question

Newsgroup: rec.radio.amateur.antenna

From: Warren <nospam@nospam.com>
Message-ID: <Htune.27839$_r1.849933@news20.bellglobal.com>
Source record: 76042

Hi everyone,

This sure seems like the group I've been looking for.

I've been researching GMRS/FRS handheld radios and have been a little disappointed in the "bubble-pack" radios that are commonly available for this radio band. The first thing I learned about was how ridiculous the manufacturer's power ratings and claimed reception distances were. I've decided to ignore the marketing & sales hype and just try to understand the basic physics of radio.

The one thing I think I've learned is that three most important components of a radio are the antenna, the antenna and the antenna. Most consumer GMRS/FRS radios come with a three inch or less antenna but I've seen some with a 1/4 wave antenna. My understanding is that FRS antennas can not exceed the gain of a 1/2 wave dipole and they can not be interchangeable, so you have to make the correct choice when you buy the radio. I have some basic understanding of the general theory of antennas, and someone suggested to me that a 1/4 wave antenna could suffer a 2dB signal loss compared to a 1/2 wave antenna. I'm interested in learning the additional dB loss in going from a 1/4 wave to a 2-3" "bubble-pack" antenna.

I guess where I'm coming from is that I'm wondering if, all other things being equal, can I realistically get equal or better reception with a pair of 0.5 watt ERP radios with a 1/4 wave antenna versus a 1-2 watt ERP radio with 2-3" antenna. The advantage of broadcasting with only 1/2 watt is very desirable from a battery life point of view. I believe increasing the power at the antenna from 1/2 watt to 1 watt or 2 watt gives me a 3 to 6 dB increase in signal strength, respectively. If the 1/4 wave antenna on the 1/2 watt radio has a 3dB or better gain on both transmit & receive units, due to better antenna design, I've achieved the same radio performance with longer battery life, all other things being equal. I guess I'm asking if there is any information that can help quantify the differences in the two types of antenna design?

There is an excellent limited, and free, Smith Chart program at this site:
http://www.janson-soft.de/seminare/dh7uaf/

Scroll down and look for the for the following, download (308 kB), and
unzip. The link below may also work from this posting.

Smith V1.91 (Smith.exe), Smith-Diagramm-Programm (Download hier):
Demo-Version der FH Bern f�r Win (bis zu 5 Bauteile, L, R, C, Trafo, Stubs
und Trafo-Leitungen mit verschiedenen Wellenwiderst�nden, kein.

A few moments playing with the program should reveal the simplicity and
power of the Smith Chart. The program was developed at the University of
Applied Science, Berne.

73,

Frank

The Smith Chart is relatively easy to learn in steps. First step
is to learn how to normalize impedances and plot them on the
Smith Chart. The 1.0 in the center of the chart is the normalized
Z0 of the feedline.

For me, the biggest advantage of the Smith Chart is that I can
carry it around in my head. It is a graphical math model of
a transmission line. A picture is worth a thousand calculators.

It shouldn't be too complex to estimate the element length of an antenna partially supported in a dielectric.

An engineer at work was assembling a 900 Mhz reference dipole for me. He did a beautiful job supporting the elements with a hand sawed polyethylene yoke. All was great until he tuned it up. He could not find the resonance point where he expected it should have been. It resonated much lower than expected for the rod length. What I figured was that the portion of the dipoles which were mounted within the plastic yoke were influenced by the velocity factor of the polyethelene. I calculated the percentage of rod length so affected, versus the portion in freespace and surprisingly was able to pin down that the resonance was where it belonged for the mechanical length of the dipoles. We then trimmed the rods down and were satisfied with the resonance.

Cecil,

Aramaic is a not Arabic. If you read the Quran, you will see that
allah is very limited as he only speaks Arabic. Of course English
translations are perverted and not as accurate as the Arabic Quran.

Jesus lived many hundred of years before Mohommad twisted and invented
Allah. And don't give me the story that Allah is Arabic for god. In
context, Allah is a personal name, not a general idea.

The Christian God is not Allah, and Jesus never prayerd to Allah.

Enough said,
Randy

The mention of the Smith Chart and slide rules in the same breath brings back a lot of memories. They put meat and potatoes on the table for me and my family for many years. I was fortunate to be in the right place at the right time at the beginning of space exploration, during which time I had the rare priviledge of developing antenna systems for several different spacecraft while working at the antenna lab of the RCA Laboratories, and at RCA's Space Center, the RCA Astro-Electronic Division until I retired in 1980.

The most challenging assignment was developing the antennas that flew on the World's first weather satellite, TIROS 1, and several of its successors. The challenge involved developing a transmitting antenna array that would radiate right-hand circular polarization from two transmitters and left hand circular from two other transmitters. The four VHF transmitters operated simultaneously on four separate frequencies in two non-harmonically related bands.

The real challenge was in developing a matching circuit to couple the four transmitters to the single antenna comprised of two crossed dipoles. The circuit was constructed entirely of printed circuit stripline transmission line.

The reason for telling you this is that all the calculations during the development of both the radiators and the matching circuit were performed with only a slide rule and the Smith Chart. There were no calculators or computers available at that time. Without the Smith Chart the impedance calculations would have been so tedious that the project would have failed due to the lack of time to complete them.

My Dad gave me a simple wooden slide rule when I was thirteen and taking advanced algebra. Then in my senior class, beginning at fifteen, he gave me an ivory Kueffel and Esser trig rule. While teaching electronic students in the Navy during WW2, I acquired another K and E rule, this time a log log decitrig. Then while developing antennas at RCA in the 50s and 60s I acquired another log log decitrig, this time an aluminum Picket and Eckel. I still have all of these rules in my 'antique calculator' museum.

My first calculator was an HP-35, which replaced the slide rules--couldn't believe I was going from three significant figure precision to nine and greater!

I later acquired an HP-45, then a 55, followed by a 34-C, 15-C, and a 42-S. I still have batteries fully charged in the last four calculators ready for use. And even though I have several Smith Chart programs, some of which appear in Chapter 15 of Reflections, I still use the slide-rule version of the Smith Chart in solving certain impedance matching problems.

That's the story of my love affair with slide rules and the Smith Chart.

Walt, W2DU

PS--Chapters 10 and 11 in Reflections present a primer in learning how to understand and use the Smith Chart.

88. Gamma tube?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-02 05:58:28 UTC
From: John Smith <assemblywizard@gmail.com>
Message-ID: <7exne.148$vr.5300382@news.sisna.com>
Source record: 76059

From working with the gamma match in real life--I have noticed it favors launching the signal from the side of the DE which has the gamma.

Now in playing with the gamma formulas, I wondered...
What if the gamma rod is replaced with a "gamma tube", same set up as the normal gamma, except the the rod is now a tube surrounding the element which is being fed? Something of a "concentric match", I am guessing the formula to compute concentric line Zo would come into play here, or a near equiv... purpose would be to get rid of the favored increase in signal from the side containing the gamma...

I know someone is going to suggest EZNEC--however, I am not good at drawing a tube with it!!!!

Warmest regards,
John

YOu have me on the Goldwing CB price, I wouldn't have a clue about it,
but as for the law, I don't recall where it is, but there are FCC
enforcement records that you can read on the internet at their site,
or someone has them posted. I used to read them regularly. They are
filled with enforcement letters to CBers who are using modified rigs
that are non-type accepted or non-certified. They are often fined
$8000 or more and, if a ham, they are ordered to get rid of the rig,
modify it so it can't operate out of band and then cover it in some
form of epoxy so it can't be re-modified again. Loss of license is a
risk.

It may be that only one in a million gets the FCC ticket, but then the
lotto has much lower odds (1:10s of millions) yet someone hits the
jackpot almost every day. The FCC is getting enough complaints to
start going after truck-drivers so all it takes is for that motorcycle
to be in the enforcement area when the FCC is monitoring.

Each radio has it's own finger-print that the FCC can read. Many
times, they can tell the make and model by the signature before ever
seeing the rig. I would think that the most popular HF mobile rig
ever is recognized by the FCC.

As for the local enforcement officers having permission to enforce the
illegal CBs, I believe I remember that that bill was overturned. I
hope so and am glad if it was. I don't know many police that know the

difference between the CB and Ham radio. My goodness, they can't even tell the difference between a ham rig and a cell phone even when you hand them a copy of the law that tells them to leave radio operators alone.

Is it legal? No. Will he get caught? buy a lottery ticket, it may
stand a similar chance of hitting. I can't say what might happen that
he could get caught. People die of strange accidents every day and
crooks get caught even when they have the flawless plan. There is a
risk that he could get caught and the penalty would be in the
thousands of dollars. (or was the OP in canada?) Regardless, I
wouldn't recommend it. Raymond may have the better point... What is
his RF exposure?

I have to admit that this is one of the more benign suggestions for
using a rig out of band. I really suspect CB band is the safest place
to do this, but I really cringe when I hear someone say they want to
modify a rig so they can call the sheriff on his own frequency "in
case of life/death emergency." I read a lot of reports on those
too...

Hi Warren,

I suspect that if you've been lurking here long enough that, yes, you may come to that conclusion. Unfortunately, within the scope of alternatives you have considered, what you write above is simply not the answer. Yes, it is smacks of a time-honored aphorism drawn from business or real-estate (not much difference in this new investment bubble these days); but actually it is the old bottle and not the new wine that rules in this regard.

In other words it IS and has always BEEN - location, location, location.

>I believe increasing the power
>at the antenna from 1/2 watt to 1 watt or 2 watt gives me a 3 to 6 dB
>increase in signal strength, respectively. If the 1/4 wave antenna on the
>1/2 watt radio has a 3dB or better gain on both transmit & receive units,
>due to better antenna design, I've achieved the same radio performance with
>longer battery life, all other things being equal. I guess I'm asking if
>there is any information that can help quantify the differences in the two
>types of antenna design?

A perfectly reasonable question, but location will eclipse these gains you've researched - many times over. Height is always king of the mountain. The ability of one antenna to "see" another antenna trumps all aces, even if both antennas are crummy beyond compare.

Height is also far easier to obtain than the constrained gain you describe. Hike that antenna ten feet for 10dB gain, or try to limp along with 3 to 6dB with a huge investment in someone's "state of the art antenna design?" The numbers will forecast that easily.

How do you get this 10dB? Well, yes, that is more handwaving than guarantee when nothing has been said of the terrain, or perhaps the fact you live in the tallest apartment at the top of a hill. The same spin of the wheel dominates the best antenna money can buy too.

A simple rule at these wavelengths and typical power levels: The range of your antenna is measured in miles for the square root of double the height in feet of your antenna. If you have a hand held and you are standing outside (we will call that at 5 foot), then your range is 3 miles to the radio horizon. If someone has a similar hand

held (at 5 feet) your combined range (grazing the horizon) is roughly 6 miles. If they are 10 miles away, guess what? Better antennas might do the trick, but they are bucking the trend.

Now let's raise both those antennas, each to 16 feet (the peak of a roof of a ranch style house). Your range is 11 miles.

This is simplistic in the extreme, but as a basis of comparison, all antennas at this frequency share the same results of height advantage.

Now, is this a matter of gain or power? At these frequencies, not really as long as they are "in the clear" (that is, free of nearby obstructions and small mountains in that path). Ham radio communication with handhelds to the Space Shuttle is not a fantasy, and there we are talking about common antennas, and common powers, at uncommon distances (a hundred miles or more). Such is the advantage of that "in the clear" path.

Irrespective of your choice of antenna, the choice of path (if in fact you have a choice) will dominate results.

For the initiated:

If you're wanting to dis-assemble Win-dos _executables_, make me a _reasonable_ offer on SOURCER v6.55 with BIOS Pre-Processor, and ASMtool v3.07, from V Communications, which I bought new in 1995.

SOURCER makes multiple passes through executabless and produces assembly-like listings (with optional comments: eg, interrupts, types of jumps), and ASMtool produces flow-charts from SOURCER results.

Why do this? Maintenance of undocumented code, virus research, solving compatibility problems ...

I dunno about "latest upgrades". The products do what is claimed for them, ie, dis-assemble Win-dos executables, and produce flow-charts.

Nisi? Okay, "Caveat emptor".

98. 50 DB of Seperation = ? Down From 100 W ?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-02 10:07:13 UTC
From: Gary
Message-ID: <5qlt919skuu928kstqd3j93jg9u5a1pfbf@4ax.com>
Source record: 76064

I'm thinking of installing a coax switch (basically in reverse of it's normal configuration - two inputs one output) between two tuner's outputs. Both are run off of the same 100W transceiver that has two antenna outputs. That way I can switch between the two tuner's without having to switch coax connectors etc. The "MFJ" switch lists 50 DB of separation. According to my calculations (its been a long time since I've been in electronics class !) that would mean the unused port of the switch would see about ~ .0015 W applied to it's output?

I wouldn't think that low amount of power would harm the other tuner ?

Thanks in advance.

Yep, the Vernam cipher is the one and only. Good crypto depends on
good key discipline and good message discipline (padding, no
stereotypical messages, etc)

Digital Fortress and Brown's other books are so full of bullshit that
I only read them to see how full of it he could get. Just like that
other "great" author, Steven King. King seems to get paid by the word
and his prose show it.

QSL.NET is notoriously slow. I'm going to get a new web page supplier
one of these days.

> If i read it correctly, you are saying that by adjusting the feedline
> length, you have a 50 match at any band.

Close - by adjusting the feedline length, I have between a 25+j0 ohm
and a 100+j0 ohm "match" on any HF ham band. Any purely resistive
impedance between 25 ohms and 100 ohms will yield a 50 ohm SWR less
than 2:1. Most transmitters are satisfied with an SWR of less than
2:1. Any 450 ohm SWR between 4.5:1 and 18:1 (in the green zone) will
yield a 50 ohm SWR less than 2:1 if the proper length of feedline is
chosen.

> It sounds like this antenna and feed match....

It is a tuned feeder that tunes the antenna system to resonance. To
get a 50 ohm SWR less than 2:1, the dipole needs to be 1/2 wavelength
on the lowest frequency of operation. That makes virtually all antenna
feedpoint impedances fall within the green target zone.

For instance, this feedline length adjustment will not work on a 102
ft. dipole (G5RV) used on 80m. The low R and high X causes the 450
ohm SWR to be higher than 18:1 so a 50 ohm SWR of 2:1 is impossible
without a tuner or network.

Here's the math:
450/18 = 25 ohms 50/25 = 2:1 SWR at current maximum point
450/4.5 = 100 ohms 100/50 = 2:1 SWR at current maximum point

Reg, you've aroused my curiosity on three points:

Why would you use 'Smith Chart' and 'anger' in the same sentence?

Why are there any frequencies where the Smith Chart is misleading and useless?
Which frequencies are they?

How can you say the Smith Chart is misleading and useless if you've never used
one, and never inspected one for more than a minute?

I am not aware of any atrocities committed by Jews in the name of Judaism in
the last 2000 years or so.

Whilst "those three gangs" might be closely related only the two big ones
claim theirs is the only way to salvation.

Nothing like claiming to have the only right way to pave the path to mass
crimes, e.g. the Crusades, and Stalin and Hitler in recent times.

Hmmm. I see a bit of a disconnect here. While we can compare and contrast syntactical structures of various languages forever, I'm not sure I agree at all that this is what I've been discussing.

The notion that syntax is the only difference between languages, especially in the context I've been giving, is not accurate at all. I certainly was not arguing syntax can be used to measure worthiness or success of a language.

My comments should be taken as musings on the nature of working coders, and the tools they need to succeed in different environments. Syntax is almost a non-issue when one takes this view.

I mean, COBOL has a pretty "interesting" syntax which has not stopped it from becoming a highly important part of most of our lives. Your bank, insurance company, investment company and telephone company all depend on COBOL, and will continue to do so for years to come. There will be no sudden change, especially not to Java or any C-like language.

The reasons for this have nothing to do with syntax, and everything to do with long-term stability and scalability in the mainframe environment.

> All which stands clear to me is that "C++" can do all of what the others
> might achieve, combined (barring assembly, which is the root of all)...
>
Any relatively complete language can do what any other language can do. However, the language is just one small part of the process. The environment in which the code is built, test, run and maintained is much more important that the language itself.

Be careful of using terms like "assembler" because this is often just another language, depending on the platform. The word "macro" in "macro assembler" means something! A CPU does not understand the text "JMP $A000" anymore than most humans.

Hand-crafted machine code via some kind of loader is pretty bare metal, but very few people do this kind of thing anymore. Even that requires a linker/loader on most modern CPUs.

>
Well, if your intention is to say that using COBOL somehow restricts
imagination and innovation, I have to respectfully disagree. A language
is just a tool, and the differences between the languages amount to no
more than flavours, in my experience.

That is, I don't see much of a gulf between coding in C, Java,
Objective-C or COBOL, other than language structure. One's approach to
solving problems changes, to be sure, but the notion is that one chooses
to solve problems using the most appropriate tools at their disposal.

Honestly, in the mainframe world even right now, the best tool for
solving the problems of mainframe environment is ReXX, JCL, PL/1 and
COBOL. z/OS shops support a fair amount of 390 assembler, but COBOL is
king for many reasons.

C is used on mainframes, but more as a "high-level" assembler for
drivers and services.

> I know COBOL programmers argue syntax as if their very lives depended on
> it (other languages too, to at least a degree), why has always been a
> complete mystery to me, in the end I just chalked it up to fear of
> "C"...
>
Do they? I hadn't noticed. There are "shop standards" and there are
finer points of where to place that final full-stop. However, the
stickler for syntax is the compiler itself. Most maintenance coders I
know have a healthy disrespect for all languages and often make wry
jokes (i.e., "gallows humour") at their own expense. Given that C is
available on mainframe I don't think anyone is really afraid of it.

Not unless you are concerned with buffer overruns, memory leaks and
stack-smashing in your mission critical application. Then you are right
to be very, very afraid of C or C++.

When you maintain a large body of code for many years, it is important
to pay attention to the details. If you check in changes around my shop
without paying attention to whitespace and bracing style, your changes
get rejected. This is generally considered a good thing.

> To try to give you a perspective of how this looks to me, the guy with
> cobol looks like he is standing there with a sliderule in hand--the "C"
> programmer as having a graphing scientific calculator in hand... both
> can get the job done--I just expect to obtain better results from one...
>
Yikes. This is sort of a naive way of looking at things, isn't it?
Expecting better results from a coder simply on the language choice is,

in my experience, the road to hell pave with all kinds of good intentions.

The difference between something like COBOL and C is not at all how you describe it. COBOL is not some kind of stone-age tech that has fallen behind. If anything, C has been pushed deeper into it's original niche of a tool to generate object code for operating systems (specifically, Unix-like operating systems.)

This is not a bad thing because this is one of the things C does best, but it does make C a bit like the slide-rule language of yore. I think of it as a compact and arcane tool that the original east-coast geeks invented as a "high-level assembler" on early time-sharing systems they were inventing at the same time.

Similarly, COBOL is an arcane and much larger toolset that, along with a whole spectrum of tools, was invented to solve another problem altogether. It just happens that this particular "niche" is much, much bigger than any of the other niches.

Certainly COBOL standards have been updated more recently than C; I suspect we may never see another ANSI/ISO standard for C again. Some might argue that this implies the language is "perfect"; that the C specification has reached a point where it represents the pinnacle of achievement for the language.

I think this horse is dead.

On Thu, 2 Jun 2005 08:58:25 -0400, "Walter Maxwell" <walt@w2du.com>
wrote:

>Why would you use 'Smith Chart' and 'anger' in the same sentence?

Hi Walt,

You've made the mistake of taking Reggie seriously for the wrong points - but as it was by his design that you do so, you can be forgiven. Walt, please note that all occurrences of "You" are meant to apply to the general reader. Those general readers may now turn their attention aside as I diverge into meaning, a dark arena few enter fully prepared to emerge from.

As much as he rails about my "Shakespearian" language - style, nothing else; his own - style that is - is as a Primitive. For many who have little appreciation or training in the arts (writing being one of them), being labeled a Primitive is not demeaning, it is merely descriptive. As I offhandedly pointed out in another post, mine is a Norman style to his Anglo-Saxon. The difference is not intelligence, but persuasion. In other contexts, like religion, one might use the word fundamentalist; hence the allusion drawn in the sentence you responded to that ties together two disparate worlds as though the association were an ethical choice. Reg could have as easily compared varieties of wine to a Smith Chart - a gustatorial choice, but still a primitive or fundamental balance. (Myself, to extend the metaphor of religion, I would offer catholic choices.)

For either of us, if you simply divorce the style, content will emerge, and I promise you find nothing to argue with. Unless arguing is your only interest in posting, that is. We (Reg and I), each in our own way, go rather the long way around the barn to say something simple. I for one (and Reg by example, so I won't speak directly to his motivation) are not here to simply litter facts across the board. No you all have to suffer understanding too (as too many of you already had the facts available before you asked any question).

So as an exercise, when you strip away style, what is left is:
>> But I do appreciate the love and respect you all have for it.

clvrmnky:
Real processor instructions are numbers, binary, they can be visualized in one and zeros, but much easier on the hex, 16 base, system.... of course assembly language has a syntax... but with its syntax, for the most part, one single instruction translates down to one or two processor instruction(s) (number(s))(and there are even exceptions to this--macro processors for example)--in a high level language one instruction can translate to hundreds if not thousands of instructions on the processor level.

Well, arguing cobol when technical uses are intended is moot. You would need an assembly language programmer to even begin--the language simply does not have the constructs to be used effectively and would need to be created.
Except for my first entry into the field, I have always avoided business related programming (cobol/basic--so I am not well voiced to argue bank coding) like the plague (my avoidance is NOT always successful even today.) Writing the interfaces to hardware (drivers) has always interested me the most--but I do diverse projects and always there is the boring maintenance and adjustments for cracked code which hackers have caught on to (this can get interesting.) However, where I presently find employment, ALL programs are in "C". From our in-house--marketing, sales, business end--right down to the drivers.

Back in 1995 there was a battle here to drop cobol and standardize all our stuff around "C", the older cobol'ers won out--then in 2000 a lot of our business code was contracted out and we ended up with no in-house cobol ONLY programmers (right to the bitter end when they lost their jobs, they argued for cobol!!!--they should have popped back to a few classes and picked up "C":)... luckily, shortly after this time, we were able to argue we should center all our code on "C" and not allow outside programmers to be aware of the functioning of our code (just then, as luck would have it, virus's, trojans, etc helped make our point for us), this allowed us, in-house, to translate the cobol to "C" and we now maintain all our code in-house again--kinda luckily for guys like me which still need a job.... (the department head here is as crafty as a wizened old fox)

I would hate for a guy over in India or China to be doing my work right now... and I keep my fingers crossed--it could easily just happen...

Warmest regards,
John

I guess this was too much work for anyone else [g].

There is a repeating pattern, but at the first frequency of ~3.2296
MHz the input Z --> infinity and the phase changes sign. It looks
like a parallel resonant circuit.

About 1973 I was tuning around 7.4 Mhz in the wee hours and heard a bunch of very strong strong SSB stations yakking amongst themselves ham style. They didn't identify and they didn't use personal names, they just chatted at each other about anything and everything. Every time one of 'em dropped the mic button there was a sharp "click" instead of a traditional roger beep. I listened for maybe 15 minutes and decided I'd wandered into some freebanders and dialed the FCC monitoring facility in Laural. The FCC op tuned the freq while we were still connected. After he listened for a few seconds he told me "That's a U.S. Navy Atlantic Fleet shore station net, they babble for hours somewhere around that frequency every night."

Oops.

Well, real processor instructions are microcode, or (at some point)
fields of electrons doing little controlled dances across the gates of
semiconductors. We aren't really talking about binary values anymore
because even this is an abstraction. It's not like anyone uses a keypad
and/or mechanical switches to load values into a register anymore.

However, assemblers were, and still or to some extent, seen as
high-level abstractions to facilitate code maintenance and readability.
This, of course, is why we have such a thing as computer languages.
Most of the time we don't care if the macros we see in a text file
correspond directly with a particular instruction.

Heck, for application programmers the further one gets away from
thinking about "instructions", the better!

> Well, arguing cobol when technical uses are intended is moot. You would
> need an assembly language programmer to even begin--the language simply

> created.
I'm not sure what you mean. While it may be handy to think of
machine-coders as the "starting point" for all things, this is not
really how it works. Most high-level languages are written in other
high-level languages.

Of course, many people take issue with the whole high vs. low level
approach anyway. Languages like C and Forth are certainly low-level if
you look at them the right way. This is one of their strengths.

However, being closer to the metal is not always better. The whole
notion of computer languages is to find a way to describe a solution to
a problem space. There are some spaces

> Except for my first entry into the field, I have always avoided business
> related programming (cobol/basic--so I am not well voiced to argue bank
> coding) like the plague (my avoidance is NOT always successful even

> today.) Writing the interfaces to hardware (drivers) has always

> in-house--marketing, sales, business end--right down to the drivers.
>
This makes sense. C was designed as an object-code generator for things like operating system librarys and (now) drivers. C can often be thought of as a portable assembler.

The age of writing applications in C (ANSI-C, anyway) is probably long over. We have much better tools to solve that problem. Hey, I like C, but I recognize it's weaknesses. If COBOL is wordy and has a strange idea of when a "statement" is (or is not) over, then C is too dangerous in the enterprise, and requires coders with a fair amount of experience who know how to use a debugger and enjoy assertions!

But it pays my bills, as does COBOL and Java. My Pascal work lives on in the form of Delphi. I suspect that in the future dependence on a specific language will diminish in favour of deployment platforms like .NET and such. Who knows, maybe the next time we talk Google will be a complete internet development platform?

At any rate, this whole thread was prompted by the earlier comment that somehow COBOL is obsolete and that nobody uses it. My introduction to the language (not my choice, either) has enlightened me somewhat to the fact that this is just not the case. In fact, the exact opposite is true right now, and is unlikely to change until someone can come up with a tool for the same problem space that offers the same necessary qualities.

It is not just that old-timers are reluctant to see the light and move to Java or C (or rewrite all those thousands of lines in machine-specific assembler.) The space that COBOL is in cannot be replaced (not without a lot of pain and significant risk) by anything else right now. The "right" kind of Java environment is a likely candidate in the long term.

Anything else I've mentioned is secondary to this point.

I've said it before, but it still bears repeating: I'm glad my bank depends on mainframes and COBOL. Uptime measured in years and performance in thousands of transactions per second (with rollback) is a Good Thing!

Cecil Moore <w5dxp@hotmail.com> wrote:

>Years ago, experiments were carried out with chaotic keys.
>Wonder what happened to that notion?

Depends how you use 'em.

As far as I know, the "one time pad" system is still used for certain communications which require extremely high security. The key is as long as the message itself, is generated via extremely-random processes (e.g. monitoring radioactive decay, listening to RF white noise from deep-space sources, etc.), is used only once (it's exclusive-or'ed with the message), and is then destroyed. Since there's no regularity in the key, and no re-use of any portion of the key, there's no way to analyze the cipherstream - any possible plaintext is equally probable.

The biggest limitation to this system is that it's very clumsy to use. You have to generate a *lot* of truly-random key, and then manage to distribute it via a physically-secure channel (e.g. CD-R discs hand-carried by an armed courier) and keep it secure (tamper-evident seals on the packages, etc.). I believe this system is used for certain military and intelligence data, but I'd be sorta surprised to see it being used in commercial applications.

For less-secure cryptosystems, the problems seem to break down into several categories: the strength of the algorithm itself (e.g. are there any cryptanalytic attacks which are significant more efficient than brute-force enumeration of all possible keys), distribution and sharing and use of the keys, and the integrity of the coding (e.g. did the algorithm or the implementation code contain a "subliminal channel" which "leaks" information about the message or key?).

Keep your eye on eBay. Chances are good that you can pick up the
exact model you had before, either used-in-good-condition or
new-old-stock, for a reasonable price.

I'll admit that there's a danger to this, though. I started
collecting slide rules a few years ago, out of nostalgia, and got
bitten by the bug. I'm up to about 40 of them now... everything from
little 5" slipsticks, to an 8" circular, to an Otis King L cylindrical
in really fabulous condition. There are even a few (a Concise
circular, and a Pickett aluminum rule) with specialized X/L/C/F scales
for doing resonant-circuit calculations.

clvmnky:

The only time I ever used a keypad and programmed directly in hex was college... it was a beginning class where you had to develop your own simplistic compiler and linker to run on a motorola processor, to gain understanding at the workings of a processor...

My C compiler/linker will go "Dennis Ritchie"/ansi/OOP/etc... there are compiler directives to allow or bar any encountered standards--I always run "wide open", if it is assembly to complex OOP macros the compiler never complains (except at real logic/language/syntax errors and missing libraries)... however, we call the winapi directly when in windows, the UNIX kernel directly when in UNIX/Linux... or assembly to deal with an LCD screen and ports if on the microcode of motorola cell phone, etc...

We have developed in-house source/binary libraries, both static and dynamic and seldom go to a 3rd party vendors (M$ SDK/DDK is used for windows NT, sometimes, mostly kernel device drivers)...

Frankly--I live a coders dream (well, something like that)... <grin>

Warmest regards,
John

>alone.

I checked, and it appears that the bill passed back in 2000. It
amended the Communications Act of 1934, adding subsection (f) to USC
47 chapter 5 subchapter III Part I Section 302a [whew!].

The new subsection allows a state or local government to pass a law
which forbids the use of any CB radio not authorized by the FCC,
and/or the unauthorized use of CB equipment on frequencies between 24
and 35 MHz. In effect, this subsection overrides the general rule
that only the FCC has jurisdiction over radio operation - it grants
local governments the right to claim a limited jurisdiction in this
case.

So, the local police don't end up enforcing an FCC regulation
directly... but they can enforce a *local* law which has the
same effect, if the local government chooses to pass one. If the
local government doesn't pass a local law to this effect, the police
have no jurisdiction.

There's a whole bunch of verbiage about appealing local decisions to
the FCC, about the FCC's responsibility for providing technical
guidance to local governments about doing this right, etc.

For the gory details, see http://uscode.house.gov/download/pls/47C5.txt
about 40% of the way down through the text.

It's possible that this subsection has been challenged in court, or
even overturned, but I'm not aware of any case in which this is
happened.

I have no idea how many state and local governments (if any) have
passed laws, or prosecuted illegal CB operation, under the authority
granted by this subsection.

Thanks, Wes. And in case anyone missed it, since the input impedance goes to infinity, you're delivering no power to the input, so there is no voltage across the load. The transmission is a comb of notches, spaced in frequency by (speed of light)*(v.f.)/(total length of line) -- in this case, 3.2296MHz as Wes says. In other words, the first notch and the notch spacing is equal to the frequency at which the total line length is one wavelength. If the difference between the two line sections is small and they have loss, the notch is not very deep. If you could actually get lossless line, it's a way to make very narrow, very deep notches, but then if you could get lossless line, you could probably also get lossless capacitors and inductors and make deep, narrow notches with them.

On the other hand, if you have a wavelength of line connected in a loop and put a load 1/4 wave from a source (which is 3/4 wave around the other direction), you get quite a good notch even if the line is slightly lossy. Look up "hybrid junctions" for more info.

Cheers,
Tom

Dave:

The T-Match will still show a favor in signal launch because of the
imbalance of the gamma rods on one side, on a beam this could even be
manipulated to ones favor--not as likely on a monopole... just looking
for a way to completely balance the field pattern...
I just thought someone had most likely done something like this
before... if I don't hear of anyone, will shove some various sized
drain, stove pipe, soldered cans, etc. over a 1/2 monopole in place of
the gamma rod and check it out this weekend...

Warmest regards,
John

A T-match is balanced because it is right+left gamma
matches, i.e. gamma rods on both sides with two equal
series caps (or tube caps).

if you do a T match like telrex used on their monobanders there is no
favored side, the two T arms were fed with a 1/2 wave phasing line and
required no capacitor so everything was at dc ground. very simple to build
and definately balanced.

Cecil:

Sorry, didn't mean that sort "balance"--as in a balanced antenna... you are right to make me be more specific...

...rather, I mean in the radiated rf field pattern of the antenna itself--because the T-Match is only on one side of the driven element--the radiation will not be completely circular (as in a vertical)--and will begin formation of a stronger pattern in one direction over all other directions on a compass, this is in reference to a vertical monopole, but still would be in effect in a horizontal version, in affecting a stronger pattern in one direction.... (and of course, there is no such thing as a "perfect" pattern, just degrees of more or less.)

Warmest regards,
John

Hi, I haven't flown since 9/11, preferred to drive. I am going on a Cruise to the eastern Caribbean, and want to take my travel antenna (loaded whip with counterpoise) and small hf xcvr. Anybody done this sort of thing on a plane? Would it be better to take the rig on carry-on or in the checked baggage? Or is this a bad idea cause they will arrest me as a suspected terrorist? Ham radios are not on the list of banned items, but I had rather not bother if it will cause any glitch in this endeavor. Thanks for any info.
Gary N4AST

Dave:

Yes, the very bottom of the monopole with a concentric "gamma tube"
would be at ground level (NOT the BOTTOM of the "gamma tube", the top of
the "gamma tube" would be connected to DE with a shorting disk or
shorting strap and would be some distance up the DE, the bottom of the
"gamma tube" would connect to a series cap to tune out Jx of the "gamma
tube", and then to the center conductor of the coax.) and coax shield is
placed at the level of the bottom of the DE monopole...

Warmest regards,
John

>carry-on or in the checked baggage?

I haven't done it myself. From what I have heard, anecdotally:

- Both carry-on and checked-luggage methods can work. Carry-on may
be preferable because you'll be present when the equipment goes
through X-ray, and can explain it on request.

- It's a very good idea to have a printed copy of your amateur-radio
license with you, and another with the radio itself. Go to the FCC
web site and download/print a set if you don't have 'em
conveniently available. Also, carry a copy of whatever
reciprocal-operating-agreement documentation you'll need to
demonstrate that you have privilege to operate in the countries into
which you are travelling.

- Identify each piece of equipment clearly - a label may be enough,
but it's probably better to ship 'em in their original boxes if
available, and/or have the manual with it.

- The inspectors are as likely to be concerned about the wire and
cable and loading coils as they are about the radio... they may
look like a suspicious bomb setup on X-ray.

- Alerting the inspection personnel to the fact that you have radio
gear in your luggage couldn't hurt... maybe ask them "Hey, is the
X-ray process going to damage my radio?"

- Be prepared to explain everything, and (if asked) to plug in the
transceiver and tune it around until it hears a few birdies, so
they can be confident that it's actually a working radio.

- If you want to actually operate when you're on board a ship, you'll
need the captain's approval to transmit. Don't transmit on board a
plane :-)

My guess is that you'll have less trouble with this than my wife and I
had, getting her walking sticks approved for carry-on in Germany last
year (they were nervous about the spikes on the bottoms).

Two years ago while my son and I were returning from Canada I was scrutinized and had to show my license. This was at a crossing point somewhere between "Nowhere and Somewhere Else" ND.

I would recommend you getting a fishing pole transport tube and stuffing your antenna in it. Ship as baggage with your rig.

Where are you going and when? What kind of a sked do you anticipate?

Check with your cruise line as to being able to operate on board. Also have a universal license (what ever they call it) as you will be on board a foreign flag vessel and not under the FCC. The same applies in most ports, except the USVI and PR.

Bon Voyage
Dave WD9BDZ

Are they feeding directly off of the coax, or do they use a halfwave
(or other) balun between the coax and the T?

Seems to me that a T directly from coax could show some amount of
imbalance. The center-conductor current would have only one pathway
to feed (the T), while the shield current would have two (the other
side of the T, and back down the feedline). If the outside of the
feedline was an integral number of halfwaves down to the point at
which it's grounded, there might be enough current flow on the outside
of the feedline to disturb the balance and change the pattern somewhat.

Sticking a half-wave coax balun at the input of the T ought to resolve
this pretty well, no?

Thanks Richard,

I certainly can't disagree with your argument about location, but I was
really trying to ask if , in identical environments and all other radio
components being equal does a 1/4 wave antenna give a quantifiable signal
quality advantage over a 2-3 inch antenna. I take it your answer is no.

Gary

I got my ICOM PCR 1000 and an antenna and lap top computer to Miami from
Los Angeles (LAX), as carry on, two months ago. No trouble
It has been my experience that the rules are not consistant from day to
day with airport security regulation enforcement.

Jerry

yes, that is how most of them i have seen work. a 1/2 wave phasing line is
used to feed the 'opposite' side of the T making it properly balanced.

Check out any of the antenna handbooks for a Tee match. The driven element
is insulated from the boom and split in the middle. Each side of the Tee
taps out on the D.E. at a point yielding a 200 Ohm balanced feed. A 4:1
coaxial balun is used to transform the 200 Ohms balanced down to 50 Ohms
unbalanced.

: Just because it's in the bible doesn't make it the gospel truth.

Deuteronomy is not one of the Gospels. 8-)

That said, the fundamental related question (for a Christian) is this:

Do you believe the Bible to be the "Word of God"? Or the "Words of God"?

There is a profound difference there, and your answer to that question
reveals a lot about your faith.

(It's a mostly rhetorical question: Think about it, but don't answer,
lest you start an even bigger flame-fest.)

I"m not sure Chuck, my math with decibels is pretty rusty. I spent a couple of bucks more and got the Daiwa coax switch which has 60 db of attenuation, so I should be safe in that regard. Now if I can just keep from accidently transmitting 100 W into the coax switch when it's got that imput grounded :^)

Thanks for your input.

73 Gary.

Just got into this thread, but checked back along it to the original
question.

I think epoxies are not too good as UHF dielectrics. I know that
standard "green" epoxy-glass circuit board material is not. You might
try "hot-melt" adhesive, especially the milky-clear ones. They are
likely to be polyethylene or a related compound. Polyethylene is used as
the dielectric in many types of coaxial cable, and is pretty decent even
at UHF.

Isaac

Cecil,

Aramaic is a semetic language written in Hebrew script. Arabic is a semetic language that is written in a distinct script. According to the CAL database (which allows translation from English to Aramaic, and a concordance of all Aramaic words), allah is not found. God is found.

Allah is an Arabic word which orginial referred to a local tribal god. Mohommad adapted this name in his development of Islam. If you have never read the development and history of Islam, it is most interesting.

You are right in that Yahweh and Jehovah are the same. You are wrong in that Allah is Jehovah. Jehovah and Yahweh are used in both the Hebrew Scriptures (Old Testement) and the Christian Scriptures (Old and New Test.), They both translate a Hebrew word that has no vowels. In respect of Jehovah, the Jews would not pronounce his name or write it with vowels. Most english translation use LORD to translate this Hebrew word.

If you look at the prayers of Jesus, they are addressed to our Father. He did not use arabiac allah in his prayers.

Jews and Muslims are "step brothers" with sibling revalry.

Remember that you can love and accept a person without agreeing with there views.

Pastor Randy,

I should have pointed out, a T-Match requires a dipole, a few seem to
miss I had previously noted this is a monopole in question... a T-Match
would unbalance the RF RADIATION PATTERN of a dipole in the same way a
gamma does a monopole, there would be no gain from using a T-Match in
place of a gamma, EVEN if it could be done here...
I suppose you might be able to mount the bottom of T-Match on the mast
holding the monopole--but then, that is another experiment for another
day...

Warmest regards,

Do you really think that Jesus spoke English? Modern Aramaic has
evolved over the last 2000 years. Words have crept in from other
languages. I'm willing to bet that Jesus never uttered the Old
English word "God" during his entire life.

"Jet" is probably also in the Aramaic dictionary. Did Jesus use
the word "jet"?

> You are right in that Yahweh and Jehovah are the same. You are wrong
> in that Allah is Jehovah.

So do you believe that Yahweh is going to send the present day
Jewish people to a hell they don't even believe in? (Rhetorical)

Christianity and Islam both evolved from Judaism. Yahweh, Jehovah,
and Allah are all individual names for Elohim, which is plural.
What name does the Arabic bible use for the creator?

Is there any difference in a 1/2WL monopole element and a
1/2WL dipole element sans the T-Match? I can't think of any.

> Reg, you've aroused my curiosity on three points:
>
> Why would you use 'Smith Chart' and 'anger' in the same sentence?
>
==========
Just a figure of speech. "Anger" suggests setting about a job with
energy, determination and a sense of purpose. As distinct from mere
amusement.
==========
> Why are there any frequencies where the Smith Chart is misleading
and useless?
> Which frequencies are they?
==========
Depending on the size of the errors one is prepared to tolerate and on
the calculated parameter of interest -

Frequencies at which line attenuation per wavelength is not small.
Frequencies at which Zo is not purely real.
Frequencies at which CR is not equal to LG.
Frequencies at which the reflection coefficient is greater than 1.0

Comment : Zo is never purely real. CR is never equal to LG.
And the chart is good only to 2-digit accuracy anyway.

But Walt, you already know all this. Have you ever tried the Jones
Chart? ;o)

==========

No problem! Worked it out for myself many years ago. Some years ago
I introduced to this newsgroup the excellent book "Transmission Lines"
by Robert A. Chipman, 1968. It aroused some interest. Some of you
obtained a copy.

It has a whole chapter devoted to the Smith Chart and fully describes
its limitations, imperfections, short-comings and approximations.

But the reason Chipman included the chapter was because of the great
savings in labour and time (in HIS day and age) when doing approximate

calculations on short, low loss, HF transmission lines such as antenna feedlines for which it was designed. Which is all radio amateurs ever use it for. Hardly any amateurs ever use it in anger. It has other applications.

I first programmed a computer for work on transmission lines around 1960. At frequencies between 0.1 Hz and 1 MHz, frequencies at which nobody would dream of using a Smith Chart. So I never became addicted to it.

Reg.

Not that I am aware of, only thing is there is no where to "hang" that
T-Match--well, the mast I mentioned... and the fact the monopole is
absent the bottom half of a dipole element... this is especially
notable if the bottom end of the monopole is sitting on the ground...
that tends to remove all confusion... <grin>

Warmest regards,
John

There's an attenuation scale on the bottom. Doesn't it just
result in an SWR spiral instead of an SWR circle?

You're right, Reg, I do know this, but as Cecil has just now beat me to the
punch, the attenuation scale that goes with the Smith Chart allows the complex
impedance loci to spiral inward with line length for any given value of line
attenuation. The loci is a circle only for lossless lines, but you already know
this.

I used the Chipman tome since around 1969, shortly after it was released. Interesting that you introduced it to this NG in 1968, but I didn't learn of this NG until the 1990s. I have two copies, one at each of my homes in Michigan and Florida.

Very interesting, Reg, but of course I knew of your many years of work with undersea lines, so use of computers around 1960 doesn't surprise me. A little bird told me one day that those lines aren't lossless. But, shucks, I coulda found that out if I'd only dug deeper into Chipman, couldn't I?

Thanks for the informative response, Reg,

Walt

Hi Walt,

I'm sorry to have the distinction of telling you that you have now
twice tried to bite at air in two postings to the same thread.
[Outlook Express is a jinx for you to use!]

There is no "John Smith" corresponding to this group. Brett uses this
"handle" for whatever reason, but certainly not because he thinks that
his veil is impenetrable.

John, your father was a genious. His pioneering in the field of wave guides at Bell Labs is legend. I also have his book, "Electronic Applications of the Smith Chart," from which I drew many concepts for use in Reflections to disprove prevalent myths concerning SWR and other mechanics of reflections. Consequently, there are many references to his book in mine, including two entire chapters to aid in learning how to use his Chart.

Holy Cow, Richard, you've just diagnosed the pain in my jaw. Silly me. I guess that means that the 'John Smith' we're corresponding with came over on the Mayflower.

I have done assembly language programming on many platforms, from 1620s to Intel to zSeries. (The most fun was the 7090 series; the least fun was Intel.) The concept of assembly programming to obtain the last ounce of performance is becoming questionable, at least on mainframes. Best performance, when considering superscalar operation, pipelining, cache boundaries, and virtual memory translation boundaries (TLBs on mainframes) no longer involves straightforward instruction streams, but needs to interleave all these other consderations that are definitely not intuitive to an assembly programmer. Well-written compilers can usually do a better job. Of course, the compiler (or optimizer that follows the compiler) must be very well adjusted to the hardware that will execute the program.

I am not a COBOL programmer. However, I do appreciate a few attributes of COBOL. For example,

- It allows creation of in-program "subroutines" with full access to the program's symbol table. (I.e., use the PERFORM verb.) Very few other languages (other than assembler, of course) allow this.
- It deals with strings as primitive elements, something the C does not do. When running on hardware (such as mainframes) that also deals with strings as basic elements, this allows for much more straightforward use of the instruction set. (The requirement for C programs to frequently chase the end of character arrays to deal with strings, and the common need to reserve a character (x'00') to mark the end of a string, has always seemed rather primitive to me. Of course, it was needed on the hardware used for early C---it is unfortunate that the language never progressed past this hardware design limitation.)
-The average COBOL program is almost certainly easier to maintain (years later, by another programmer) than the average C program. Of course, one can write obscure code in any language or wonderfully clear code in any language, but I am speaking of existing, average code. (The extreme example in this category was APL. Even the original programmer could often not understand his own code after being away from it for a few months. It was a wonderful, powerful language, but the average program was utterly unmaintainable in typical production environments (in my opinion).)

I have noticed that major applications written in C (or C++) appear to consume considerably more processor power and considerably more memory than applications written in COBOL (or assembler, or PLI, or Fortran). A 1MB application in COBOL is "large" while a 1MB application in C is almost "trivial". I know a lot of this is due to the inclusion Windows libraries (DLLs), etc, etc, and the different nature of the applications.

There is seldom a winner in religious "discussions" and I suspect this thread is about to die.

Hi Walt,

I won't accuse you biting air on this one, again, Reg is in his usual
yarn spinning and this time both of you evidence the myth of those who
"use" a language believing they "know" that language. Brits are
terrible exemplars of best English usage. So are Americans, but they
rarely behave like they own the language they dominate (that is
changing as we write - the rest of the world is going to soon claim
that crown).

Reg has in fact fallen off the Anglo-Saxon wagon (or should I say
cart?) by trying to fit a new definition to an Old French import to
our common language. In a way, he has succumbed to the worst traits
of Americanizing English through cavalier redefinition.

Anger has always (to English speakers at least) meant just what you
thought it to mean - relating directly to the sense of pain or
affliction. Somehow Reg wants to convert those rather daily
experienced negative associations into something bright and cheerful.
Perhaps he has been reading too many missives from our White House's
pronouncements on the conduct of the war....

Anger comes by way of the Old French anquisse, or the Modern French
angoisse, derived from the Latin augustia meaning compression. Most
folks do not smile in anticipation of anguish becoming their "sense of
purpose." Not unless you are a fundamentalist perhaps.

Who would'a' thunk that this thread could be such a trove of language
instruction? ;-)

From my copy of the "Concise Dictionary of the English Language"
(available at project Gutenberg):

Angre ... affliction, sorrow, wrath, pain, inflammation ... by way of
the Icelandic angr.

Angren ... to annoy, injure, make angry ... by way of the Icelandic
angra.

Angwisch ... anguish

anguyssh ... angoise

anguise ... anguisse ... angustia, tightness from angere, to squeeze.

Amusingly enough, every one of these terms encountered in line are
directly following:

Angles ... the English, the people of 'Angul' a district of Holstein
... Englis.

What a larf (or for the rest of the English speaking world, Hoot).

Bill:

I actually do not stand at complete odds with you...
However, "C" can be viewed as a "superset" of assembly...
Or, assembly can be viewed as a subset of "C"...
I am aware of no "C" compiler which refuses to accept assembly language instructions--as standard... I am aware you might have to set compiler directives to allow or disallow this as you see fit...
For one who declared, right from the start, that religious wars on syntax are exactly what I wish to avoid... I seem drawn like a moth to a flame (or something like that)...
However, since we have gotten here, to this point, let me go further, if I would choose to write in COBOL syntax--I would still keep my "C" compiler and linker---and, would use the #define and statement, and macros in "C" to remap all of the COBOL syntax I would use, to "C"....
I could then go about my merry business and write in "COBOL", when the "C" compiler seen the source, it would translate on the fly and produce "C" object code...
if I was not aware of what had been done--I could honestly be left thinking I was truly using a legit COBOL compiler/linker, I could do the same with pascal--even basic should I choose... attempt to do the reverse with those languages and you will see failure...

... in my humble, personal opinion, you can develop a million more syntax's, I am just left to sit and wonder why...

Warmest regards,
John

Hi Dave,

A horn is an impedance matching device, not a lens. It is generally
pointed in the direction of desired maximum radiation. If you want to
employ what appears to be the equivalent to your application of focus,
then its "throat" is the term you should be interested in (at least
from the common literature on this subject - a subtle hint, in spite
of your protestations, on how to google this).

The plane of the throat is usually placed at the focus of the
truncated parabaloid (otherwise known as the dish) and orthogonal to
the parabaloid's major axis (the line that points in the direction of
the opening's maximum radiation). Hence both are collinear (and of
necessity, the horn blocks some of the available radiation), unless
this is an off-center feed. In such a case, the math becomes a little
more involved (but all structures conform to these usages).

Regarding the long-lasting, 67-years old, love affair with the Smith Chart.

Where there's Love there's Beauty.

The beauty of a Smith Chart derives from the underlying Mathematics. Mathematics is pure intellectual beauty.

In this case the underlying functions and their inverses are the Complex Hyperbolic Functions like Sinh, Cosh and Tanh which Victorian engineers were familiar with. The behaviour of the early telegraph, telephone and power lines was exactly described by such functions. The maths had been quietly waiting for many years for transmission lines to
be invented.

In the absence of computers, engineers soon got fed up with designing transmission lines, solving complex hyperbolic equations with the aid of log tables and slide rules, and began to use graphical methods in the form of charts.

Now, complex hyperbolic functions are 3 dimensional things. They have two linear dimensions and angles. They cannot be represented on a flat paper chart. They need a whole stack of charts. Such stacks of charts were available round about the Boer War. So whilst the British Army was setting up concentration camps in South Africa, phone engineers were busy in their factory offices worrying about SWR on power and long-distance telephone lines.

The Victorian multi-dimensional charts remained in use through the days of VLF and LF radio and for 5 decades until the advent of computers. Bear in mind the charts were just a more convenient means of accessing data than from books of mathematica tables, although they were of much lower precision.

See if you can find it - "A Chart Atlas of Complex Hyperbolic Functions", A. E. Kennelly, Harvard University, 1914.

Worldwide HF radio rapidly expanded from the early 1930's. In 1938 a certain Mr Smith noticed that at HF and higher frequencies, for rough and ready calculations he had to use only one of the stack of charts. This particular chart corresponded to the case of a lossless line and when Zo was purely resistive. No real lines have zero loss or have a purely resistive Zo. But practical lines have a sufficiently low attenuation per wavelength and a Zo whose angle converges towards zero with increasing frequency, for a single chart on a flat sheet of paper to deal with sufficient accuracy calculations at frequencies down to

LF. So Mr Smith exercised his artistic talents to produce the chart we
are familiar with. Or at least which we have heard about.

Hi Reg,

A rare citation indeed, following an equally rare citation (Kennelly
following Smith, that is, and rare meaning a citation offered by you
who usually claim such activity reveals plagiarism).

But as for your challenge (yes a heated term I suppose - but
still...):
Google "Complex Hyperbolic Functions" Kennelly
to find from:
http://www.geocities.com/neveyaakov/electro_science/kennelly.html
"Arthur Edwin Kennelly was U.S. electrical engineer who made
innovations in analytic methods in electronics, particularly the
definitive application of complex-number theory to
alternating-current (ac) circuits."

Let me quickly add that Kennelly was US through immigration and
professional employment, but British schooled and trained.

Such an introduction would put your comment to the test:
>The Victorian multi-dimensional charts remained in use through the
>days of VLF and LF radio and for 5 decades until the advent of
>computers.
Which on one hand would suggest rather Edwardian than Victorian, and
on the other hand, perhaps Wilsonian for where this tome was actually
published.

I have a copy of Kennelly's "A Chart Atlas of Complex Hyperbolic
Functions", in my library in Florida. I'd be pleased to scan it for anyone who'd
like a copy, but only if you have the patience to wait until I return south in
November.

Hi Walt,

I cannot imagine that but being a very lengthy chore. However, it is
quickly becoming one that more than a few are willing to perform and I
offer to one and all my congratulations and thanks for such effort.

I will pass on this if I am your only motivation. I have a copy of
"Standard Handbook for Electrical Engineers," McGraw - Hill, that is
contemporaneous. It comes with many such charts, tables, figures, and
minutia in the classical Wilsonian style of illustration (and I cannot
imagine myself copying all 2000 pages for circulation).

217. Mobile Antenna Matching Question

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-03 19:21:37 UTC
From: wb5cys <wb5cys@sbcglobal.net>
Message-ID: <552oe.2209$RV5.711@newssvr30.news.prodigy.com>
Source record: 75883

I put a mount on my Dodge pickup, bolted to the bed rail with 4 stainless steel bolts. I placed a 20M Hamstick on the mount and the lowest I could get the SWR to drop at my desired frequency was 1.7 to 1. So I placed a small matching coil at the base of the antenna (also made by the same manufacturer as the antenna). As I started trying to bring the SWR down I noticed that anywhere that I touched the coil with the shorting wire would make the SWR rise. At the very end of the coil - away from the mounting point, the rise was minimal. As I moved the clip closer to the coil mounting point the SWR rose.

The same thing happens with my 40M hamstick.

What does this tell me? Am I doing something incorrectly in the matching process?

Thanks for any and all advice.

WB5CYS
Texas

Well, judging from the description, I'd say you need a cap
instead of the coil. It's sorta telling me you have enough
coil already. Part of your loading coil in the whip is
already acting as a matching coil. I think you probably
need a cap to tune out some reactance. I often use a
simple MFJ random wire tuner as a mobile matcher.
That would dial that down pretty low I would think.
But this is just a guess, being I can't see it...
In my trucks, I have the small tuner, and also a "dollar
special" matching coil. I use the tuner more often I
think...Most of my antenna setups with the glass stick
bases, have a few turns of matching coil wound into
the base. MK

Ever see a drawing of the gold-covered Ark? Those folded
wings look a lot like a dipole. Maybe it should have been
named the "Arc of the Covenant". :-)

From the TLC web site: "The specifications also included the two gold
cherubs that decorated the ends of the "mercy seat" atop the Ark, from
which God would communicate with Moses. These manifestations were said
to take the form of a glowing cloud, sparking between the outstretched
wings of the cherubims."

"But the Ark could be unpredictable. When the glowing cloud arced
between the cherubims, Moses himself would often keep clear of the
Tabernacle as implied in Exodus 40:35. Biblical accounts describe a Holy
Ark that seems to strike down its caretakers with the same raw power
unleashed against its caretakers' enemies. The sons of Aaron ï¿½ Moses'
own nephews ï¿½ were struck dead by the fire of the Lord. when they bring
the wrong offering before the Ark. In 2 Samuel 6:7, during a celebration
in Jerusalem, the driver of the cart bearing the Ark reaches out to
steady the golden box and falls dead at its touch."

Anything you do to a resonant antenna will usually raise the
SWR. For the coil to work, you need to start with an antenna
that is too short. You need to adjust the stinger as well as
adjusting the coil. First adjust the stinger to resonance
without the coil. Then shorten the stinger to raise the SWR
by making the antenna capacitive. Then add the coil. Alternate
between stinger adjustment and coil adjustment until satisfied.

Source record: 75888

First, I would say that 1.7 to 1 is fine, leave it alone. It is what is expected.

That being said, the strident need to be 1:1 can be met in several ways. The antenna will probably be around 35 ohms. giving you the 1.7:1 you observe. You can wind a toroid (t-106-2) with 14 turns of wire. tap one of the wires at 11 turns and feed the antenna. A 50pf cap between the antenna and ground might also prove usefull.

to wind the toroid, start with a black and white wire, wind 14 times through the hole. Connect the black start end to the coax center. Connect the white start to the black finish. Connect the white finish to the coax shield, and vehicle ground. At turn 11 of the black wire, put a tap. This tap goes to the antenna.

The SWR meter should now read 1:1 and you won't get out one bit better.

The SWR on my base feedlines are 9:1 by design. I run a screwdriver on the car and once I am below 2:1, the radio is happy and so am I.

in other words i think he is trying to make a J pole into a coaxial
arrangement where the short part of the J wraps all the way around the pole.
personally it sounds like a lot of work to get rid of some small assymetry
caused by the gamma rod. the easier solution is a plain vertical with a
tuner to make the transmitter happy.

I flew to Daytona a year and a half ago for Christmas with a 10 foot stainless whip coiled up in a large sutcase. Also included in the suitcase was a triple magnet mount for the whip, a Z11 autotuner, assorted coax. The bagchecker, Northwest Airlines at MSP, spotted me with my handheld, put 2 and 2 together, and asked if it was my bag, then said he was a ham and passed it all, no problem.

So I probably lucked out, but it for sure was all legal according to him.

Hi Tom,
I knew the band was open because of 88-108 stations booming in, but my rotor
and remote antenna switch wires to the tower are temporarily disconnected
while we build a 180 ton rock wall behind the house. I'll be back on this
weekend.

Local CATV outlet will have end of reel lengths of 1/2 and 7/8 hard-line
that should meet your needs. They have to pay to send it to land fills (so
you save them money)

I'm curious -- how did you determine from the SWR that the antenna impedance would be resistive, and assuming it is, that it would be less than 50 ohms rather than greater? Perhaps you've measured a Hamstick on a typical mobile mount?

I've carried quite a variety of interesting stuff on domestic flights many times before and after 9/11, including homebrew gear, mag mount antennas, cables, batteries, etc., and on a few international flights. My checked bags always end up with a card saying they've been inspected, but that's all. The carry-on is sometimes flagged for hand inspection by the X-ray operator, and I've learned to leave the interesting stuff on top so it's easy to find during the hand inspection. Sometimes the problem is simply that they can't see what might be hidden under a metal box (which I assume is why they require computers to be removed from their bags). If you're in a hurry, you can dump all the interesting stuff into one of the plastic bins so it's in plain sight and they won't have to search through your bag for it, and so it won't hide any of the bag contents from the X-ray -- I've done that on a few occasions. The hand inspection usually only takes a couple of extra minutes. There's nothing illegal about carrrying radio or electronic gear -- they just need to know that it won't explode, give off noxious fumes, or be used to stab somebody. If it won't, they could care less what it is or does. It's not a big deal at all.

MP3 players, USB, Ethernet, and telephone cables, GPS receivers, HTs, cell phone chargers, power supplies and voltage converters, and other common modern trappings generally sail right through the X-ray machine without a comment.

Does a knot in insulated 16g stranded wire pose a problem
for a dipole at HF freqs? This is a 66' FD dipole, coax fed,
operating 40-10m with a KAT2 autotuner. The knots are 1/2"
away from the feedpoint & lock the antenna to it's center
insulator.

Sorry, Ken, knots are a no-no. DC can travel through them, but RF? Uhn Uh. The RF gets all tied up in them and doesn't know which way to go, so the power concentrates there and pulverizes both the wire and the insulation--the knot goes pooof! And down comes the dipole. How much did you say you paid for it?

It's called "signature analysis". Every emitter, whether the human voice, a transmiiter or a piece of vibrating machinery puts out its vibrations in a unique pattern that can be determined by careful analysis of the signal. There are mathmatical analysis tools that can break down the patterns into frequency bands and time signatures that all together, show that your Icom IC-706 MarkIIG is uniquely different from my friend's. The math isn't particularly difficult, there are specialty chip sets that will do it. The trick is doing it fast and accurately enough. The "waterfall" display in WINPSK is doing the math, but only enough to show the signals and decode the PSK protocol. If it were accurate enough it would show the differences between all the transmitters.

At one place I worked in CA, we put a knot in the AC line of
our soldering irons and hung them on cup hooks on the wall when
not in use.

I was using one at a bench when a secretary asked me what the
knot was for. I told her that's how we regulate the temperature
of the iron - the tighter the knot, the fewer the electrons
getting to the heating element. Physics was not her long suit.

HI Ken, the knot would pose no problem at hf frequencies. It would
pose even less a problem if you stripped the insulation off at the knot
and soldered it all together.

It's impossible to bring an impedance greater than 50
ohms down to 50 ohms by installing a shunt reactance
so the resonant feedpoint resistance of any mobile antenna
using a shunt reactance to achieve 50 ohms is, by definition,
less than 50 ohms.

if Rs >= 50 and Xs > 0 then Rp > 50

Assume one can adjust the feedpoint impedance of a 40m
bugcatcher to 25+j25 or 25-j25 by adjusting the length
of the stinger. If one shunts 25+j25 with a -j50 cap,
the feedpoint impedance will be 50+j0 ohms. If one shunts
25-j25 with a +j50 coil, the feedpoint impedance will
be 50+j0 ohms.

My meaning above may not have been 100% clear.
I meant to say: It's impossible to bring an impedance,
having a resistive component greater than 50 ohms, down
to 50 ohms by installing a shunt reactance.

I didn't pay much for it. I had the coax & connector plus
the center insulator. The wire was $3.30.

FYI I'll only be putting 5-15 watts SSB/CW through the
antenna on FD.

The Knot matters not
your signal will live
but the receivers
will need to tie
a knot in their ears

I just had an idea - I could strip 1/2" of insulation
just past the knot and solder a jumper to the feedpoint,
electrically bypassing the knots while still leaving
them there to be strain reliefs.

Thanks for the help, guys.

I don't know. My last Rottweiler was quite the prankster. She never really displaced objects that were not defined as her *toys*. However, one morning when I was in the shower, she removed the bath mat to my bedroom and then came back and laid in its place. When I pulled back the shower curtain, there she was, looking up at me with a silly grin. I just laughed as I said "Kiska! What? You want I should stand on you and drip?" She then jumped up and brought back the bath mat!

Only going from the last one I fooled with. I was unable to persuade the owner he would be better off tuning for field strength than SWR and the solution I purposed is one of many that will make a SWR meter happy along with those folks who are cult members of the church of no reflections.

I make no claims that any other antenna in like or different circumstances will ever exhibit exactly 35 +j0 Ohms. If I gave that impression to the learned members of this conference, I humbly apologize for once again making a broad statement with out a list of qualifiers. Mea Culpa :>)

The ubiquitous SWR meter, the greatest generator of misinformation since Baghdad Bob.

Fred:

I wonder if most arent really aware that SWR is not real in a lot of cases where the term "swr" is bandied about (big deal, I don't believe in time either)--I have experienced large feedline radiation on almost perfect reading swr meters--I accept this as real--and still run with it (even if I lose 10 watts of 100, I don't sweat it anymore, heck, if Cecil splits his bottle of wine with me--I could careless about 20 watts <grin>)...

... however, I have noticed that it (the swr meter) slows the need to keep soldering new mrf4?? mosfets into the finals and linears of this new age--it is a cheap quick fix--and if transmitter loading is good, the finals are cool, I am good with it... and some just wanna get on the air... I will mess with an ant for best received signal--from there on out it is just crank power till we are at max--if needed--and if that fails a gentlemans admission of failure... and a gentleman ALWAYS uses minimum power for effective communication!!! <sly grin>

... the true art of dancing fairies on pins, and speaking in shakespeare to obfuscate the ideas which I express, and beginning to hold myself as superior in intelligence and mind games--I hold for a later date--which seems to be approaching far to fast for my liking... check back with me next week, I may have changed my mind... <grin>

263. Questions on Kenwood TKR-750 Repeater

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-04 01:21:24 UTC
From: gargaare@yahoo.com
Message-ID: <1117848084.376173.102510@g44g2000cwa.googlegroups.com>
Source record: 75829

Hello All,

We bought a kenwood repeater TKR-750 and 2 diamond F23 antennas plus
the programming software.

Unfortunately we can't hear anything beyond one kilometer. Here are the
frequencies we are using:

TX 15900
RX 16000
TONE1413

The equipment are being used in africa in a remote location for an NGO
helping refugees I am back here in the states now.

I would appreciate any pointers from the group.

Thanks.

- Nur

1,771,561 tribbles, er, electrons. That's assuming 1 trib - electron,
multiplying with an average litter of 10, producing a new generation
every 12 hours for 3 days.

Cudos to Cmdr's Spock & Dax - does that label me a Trekkie?

LOL

Need more input. How far apart are the antennas horizontally and vertically?
What filters are you using on the receiver input? I am assuming you mean
159 and 160 MHz. My first guess would be desensing, but without additional
info, it is just that.

> the programming software.
>
> Unfortunately we can't hear anything beyond one kilometer.

It appears that you are buying hardware, and believe that this is "Plug and Play" - WRONG.

You appear to lack and understanding of how to properly design a repeater system. The equipment is EASY - proper design is the VALUE (and knowledge required) to have an efficient overall repeater system.

A repeater system is completely DIFFERENT than a normal radio usage or system - SINCE the transmitter and receiver are operating at the SAME TIME !

Since you have not mentioned the usage of a cavity filter (duplexer) for this system OR the spacing of the antennas -- I assume that the transmitter is "desensing" the repeater's receiver. (Think of it as you trying to hear a distant friend when someone next to you is shouting -- that's what is happening)

You MUST either user a 6 cavity or physically space the receiver and transmit antennas sufficiently apart (horizontally or vertically) so that the receiver is NOT desensed by the transmitter (at least 60 dB reduction of the transmitter at the receiver's input.

The ARRL FM and Repeater book (1970s) covered this in detail.
The Repeater Builder's Web Site -- will likely be very instructional for you
http://www.repeater-builder.com/rbtip/

> Here are the frequencies we are using:
>
> Tx: 159.000 MHz
> Rx: 160.000 MHz

I assume that these have been approved by the government body of the African country you are operating within? If NOT, you better address this first, or you may have addition issues. Definitely not an amateur radio frequency in your ITU Region.

OK, you have 1 MHz spacing between the receiver and transmitter. This is useful for your future calculation of how much isolation (dB) that you will require.

> CTCSS Frequency (sub-audible): 141.3 Hz

I edited your value - since I think you are saying you are using CTCSS at this frequency. First get the system running without CTCSS enabled - THEN you can worry about CTCSS

> The equipment are being used in Africa in a remote location for an NGO
> helping refugees I am back here in the states now.
> I would appreciate any pointers from the group.

Sit down and read and learn how to properly design a repeater system. I know engineers who have been doing it for years -- that still have to work on final system designs. Local terrain, coverage desired, antenna location and height are all CRITICAL factors for a good design. You will should be using accurate topology maps for the area.

Call or web site visit the Kenwood Land Mobile support department (California) and ask for Technical Assistance.

Reminds me of my youth. One of my earliest jobs was working in an
automotive parts store. This was back when you actually had to know
cars and how to read and look things up in paper catalogs and stuff
like that.

One test some of the oldtime mechanics would do on a new parts guy
would be something like asking for a set of spark plugs for a Cummins
diesel, a radiator cap for a Corvair or a pan gasket for a Powerglide
transmission. I fess up... they got me on the last one.

Ken, the only problem with the knot is that the wire will be weak at
that point.

I think John is right
Even though the antenna will work fine WITH the knots
if the owner of the antenna has doubts
then the knots should be removed post - haste.
all you need is that element of doubt
when you can't quite get thru the pileup.
Was it due to those 2 knots ?
Yeah - solder a jumper - or untie them for sure.

Hi Dave.

W1GHZ has an application that will determine the focus of your dish for you.

However, I find it easier just to attach a few small mirrors on the dish
and point it at the sun to determine the focal point of your dish. See

http://www.qsl.net/va3rr/dualmode/dual_mode.htm

Now you just have to figure out where the phase centre of your feed is...

A knot in an antenna wire will have absolutely no electrical effect
below about 200 MHz.

But it will mechanically weaken the wire. During the next hurricane or
loading with ice it will be more likely to break.

Thanks to all for your helpful information on this topic. And thanks also for the notes on proximity of the operator to the antenna. This is also of a concern to me, but it's a different question so I didn't mention it in my original post.

The fact is, I'd be doing about 98 percent listening and 2 percent talking anyway, and so I'm currently somewhat more concerned about damage to equipment than damage to my brain which is already fairly damaged anyway according to my XYL... ;-)

As for opening up the 706 to transmit out-of-band, this rig has that mod (for MARS). If I didn't already have the integrated CB in the Gold Wing I might consider using the 706 on CB and take my chances on getting caught, but since the legal radio is already there, may as well use it.

Roy spurred me to type:

I use a screwdriver matched with a simple toroidal autoformer.
I tuned the antenna for a purely resistive load using an analyzer.
Turns out it was 20 - 30 ohms on 40 meters, IIRC.
Then I wound 14 turns of copper wire around a toroid, connecting one end to
the coax center
and the other to coax shield and chassis ground.
Then I tapped the antenna on to the autoformer such that,
looking down the coax, the analyzer saw 50 ohms.
I use this matching configuration for 160 - 20.
I get the best VSWR and field strength of many variations I've tried over
the years.
On the higher bands I just hook up the coax and tune for minimum VSWR at the
transceiver.

284. antenna tuner balun question

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-04 19:48:36 UTC
From: Bob Miller <NOSPAM@neosoft.com>
Message-ID: <fb04a1t0b9qa4143rh26qkbaqb32uq0pq7@4ax.com>
Source record: 75851

Having never wound a balun before, pardon if this is an elementary question, but...

I recently got a Murch 2000B antenna tuner off eBay. It's a commercial version of the so-called ultimate transmatch. A T-network design.

For balanced line, it has a "broadband toroidal transformer" according to the review in a 1980 QST. When I place a VOM multi-meter across the two balanced line terminals, it shows continuity. Is that normal, or is the balun cooked or shorted?

Thanks for any info.

Bob

It's probably a 4:1 voltage balun which does exhibit
a DC short. That's actually good for cutting down on
static electricity.

Bob:

Totally normal, in fact, if you check secondary to primary--will also
show continuity--it is normal too...look at a schematic of a torrid
balun on the net, all windings have some sort of connection to all
others... in a "rf transformer" with seperate primary/secondary there
will be electrical isolation between windings...

Very probably normal... or, at least, to be expected of many types
of balun and thus not diagnostic of a failure. You're probably
reading the DC resistance one or more of the windings, which would be
rather less than an ohm.

Based on what I see in Sevick's book on baluns and ununs, both the
Guanella 4:1 current balun and the various Ruthroff voltage balun
configurations would exhibit this behavior. A Guanella 1:1 with the
center of the load un-grounded would not, nor would a Reisert or W2DU
1:1 balun.

Now, for something completely different. If you want to revisit an
old controversy, and if you're not adverse to modifying a classic
piece of equipment, you might want to review the various debates about
the pros and cons of the Ultimate Transmatch vs. the SPC
configuration. See if you can locate a copy of the August 1981 QST,
and review the Technical Correspondence column on pages 42-43.

As I understand it, the SPC configuration can be shown to have some
significant technical advantages over the Ultimate Transmatch, in terms
of matching range and harmonic attenuation, when the same component
values are used in each. It is reportedly possible to re-wire an
Ultimate into an SPC configuration little or no cost, as both use a
split-stator capacitor (just in different places in the circuit).

Thanks, Dave, I have a 1985 arrl handbook that shows the differences
between the Ultimate Transmatch and the SPC circuit, and I also have
some modification instructions on the Murch unit itself, but I haven't
tried changing anything yet. Still playing with it, as it came.

Thanks, Cecil, I noticed a more up-to-date MFJ tuner doesn't show
continuity across the balanced line terminals; just wanted to make
sure the Murch balun wasn't whacked out.

Okay, Cecil, Dave, one more elementary question. My copy of the
instructions for the Murch 2000B says the following:

"Connect balanced line to connection marked Balance Line with Jumper
as indicated on back panel."

On the back panel, there's a painted line between the two balanced
line connections. Surely, they don't mean to run a jumper wire between
the two connections *while* a balanced line is attached?

It seems to tune fine without the jumper -- I'm afraid I'd blow
something up with the jumper.

The eBay bidding started at $100. There were 20 bids, and it finally
ended up at $171, plus $20 for shipping.

The case is a little scratched up, but the front panel and inside
components look good.

> Bill, W6WRT

Just a quick back-of-the-envelope calculation.

SWR' = 1.7

or SWR" = 1.0

Let's assume worst case; all the reflected power is absorbed in the source.
This is not necesssarily the case, but gives us the least signal strength in
the high SWR case, SWR'.

So then, comparing the two cases, the change in power to the load in db is
10*log(SWR'/SWR").

SWR'/SWR" = 1.7

2.3 db, barely detectable, worst case.

So it's a question of how much reflected power can the rig tolerate as well.

No, I think the painted line is meant to indicate "the line is
connected to/between these two points." The "jumper" they refer to
probably refers to a short section of balanced line, to be connected
between the transmatch and whatever terminals you use to terminate the
ladder-line or open-wire line when it comes into your shack.

>It seems to tune fine without the jumper -- I'm afraid I'd blow
>something up with the jumper.

Yeah, you'd be trying to tune a near-short-circuit... often difficult
and the results are less than productive :-)

There are some transmatches in which the balun is normally out of
circuit, and has to be jumpered to the hot side of the unbalanced
output when you want to use it. That *might* be what they're
referring to?

IIRC, the 7th was using US issue single-shot, rolling block rifles. Studies of the distribution of spent cartridge cases indicates that the Indians had quite a few Winchester repeating rifles. Further, Custer had left his battery of Gatling guns far behind, as he felt they slowed his maneuver ability.

If it's like my MFJ-949E, the balun is completely out of the
circuit until the jumper is installed. Without the jumper on
the MFJ, there would be no output at the balanced line
output terminals. Do you have a schematic?

I've always wanted to go back in time and take a few
Gatling guns back to the Alamo - and maybe a few cases
of hand grenades.

That calculation completely baffles me.

The ALC in my Icom rig keeps the forward power constant up to the point where it reduces power, at around 3:1 SWR. This is typical for commercial rigs. The rig delivers 100 watts to a 1:1 SWR load. (Techically, this really means a load which, if terminating a 50 ohm line, will produce 1:1 SWR on that line.) 1.7:1 SWR is a reverse/forward power ratio of 0.067. The ALC keeps the forward power at 100 watts, so with 1.7:1 SWR, the reverse power is 6.7 watts. The net power delivered to the load is 100 - 6.7 = 93.3 watts, or 0.3 dB, not 2.3 dB, less than the power delivered to a 1:1 load.

Oh, and the "reverse power" isn't "absorbed in the source". Anyone interested in learning more about this might take a look at "Food for thought - Forward and Reverse Power.txt" at http://eznec.com/misc/food_for_thought/.

Sorry, I don't have a schematic.

On my MFJ 989c, I have two balanced line connectors. I also have a 3rd
connector for Random Wire, and a 4th odd connector. For balanced line
operation, I install a jumper between the Random Wire and 4th
connectors.

On the Murch 2000B, there are two connectors for balanced line. And a
3rd connector for Random Wire. The directions seem to be saying put a
jumper on the balanced line connectors for balanced line operation.

"Connect any antenna with single wire feed to connection marked Random
Wire. Connect balanced line to connection marked Balanced Line with
Jumper as indicated on back panel." (and there's a painted line
between the Balanced Line connectors.)

If it's helpful, there are pictures, inside & out, of the Murch tuner

I would disagree with your statement about SWR being absorbed in the source.
The reflected wave is rereflected and aside from losses caused by the 2 way
trip is reradiated.

While your math is correct, your application in my opinion is incorrect.

I suspect the jumper wire needs to go between the random wire
terminal and one of the balanced line terminals. That's the
way it is on my MFJ. On the inside, do the balanced line
terminals go anywhere besides the balun?

Reflected current flowing into the final amp can superpose in
phase with the forward current and, without protection circuitry,
cause the final amp to exceed its dissipation rating.

Another possibility is when the reflected voltage superposes
in phase with the forward voltage, and without protection
circuitry, exceeds the voltage rating of the final.

If all reflected power was always re-reflected, there would
be no need for protection circuitry. The generated power is
defined as the forward power minus the reflected power. That
does NOT mean that the reflected power is 100% re-reflected.

According to one note I saw on the net, many of the Ultimate
Transmatch designs had an internal strap/jumper to connect the
unbalanced tuner circuitry to the balun, when necessary.

I rather strongly suspect that this is the case for the Murch. The
photos show that it has internal switching of the tuner output. The
switch has five positions - 1 2 3 (which I assume correspond
to the three unbalanced jacks) and two I can't really read clearly in
the photo - perhaps the random-wire output, and the balun for the
balanced output?

Sounds to me as if no external hot-to-balun jumper is requires,
especially as the OP reports that it tunes a balanced antenna just fine
without one.

One Balanced Line terminal goes to a balun winding wire. The second
Balanced Line terminal goes to another balun winding wire; the second
terminal also has a wire going to the Antenna Selector Switch, which
selects the balanced antenna. The Random Wire terminal has a wire
going to the same Antenna Selector Switch, which also selects the
random wire antenna.

Those are the only wires on these three terminals.

That's right, the 5-position Antenna switch selects coax 1, 2 and 3,
and R for Random Wire, and BL for balanced line.

Hi Fred,

I've seen this thesis offered before. I generally ask, since this is
exactly the same thesis offered for a conjugate match offered by a
tuner, and a tuner is used for this very purpose (rereflecting the
mismatch), if the Transmitter already does it - What is the Tuner for?

Why do you use a tuner? What is a match? Why would anyone seek to
match a Transmitter to its load?

Richard, I'm afraid I don't understand you. And I doubt if anybody else does either.

For some inexplicable reason you have reverted back to Shakesperian poetry.

Come back to plain American English. Try the other English (or Irish) playright and iconoclast, George Bernard Shaw.

And I hope you don't object if I begin some of my sentences with 'And'.

I guess I wasn't able to divine your intent, then.

You say you have a surplus DirecTV "feed". You say you know the focal
point of your dish. You want to use your own 2.4 GHz feed. You
make mention of an adjustable feed - is it a chapparel-type feed because
I didn't think the DirecTV feeds are adjustable?

What kind of horn are you planning to use for 2.4 GHz? DirecTV dishes
are usually fairly small - the more efficient feedhorns are fairly
large, at least for 2.4 GHz if you have a .7 f/D DirecTV dish.

The simple answer is to place the phase center of your 2.4 GHz feed at
the focal point of your dish. What is the phase center of your 2.4 GHz
feed? Maybe this is the question you want to ask. If so, the answer is
probably here.

Texas separated from Mexico and was an independent country before it ever
bcame part of the US.

Texas was actually stolen four or five times and one
time Mexico was the thief when they stole Texas from
Spain. Texas was originally stolen by the Europeans
from the Indians who thought owning land was a ridiculous
concept.

That's different from the MFJ which has wires from the balanced
output terminals going only to the balun.

> The Random Wire terminal has a wire
> going to the same Antenna Selector Switch, which also selects the
> random wire antenna.

MFJ saved money on the switch by combining the balanced and
random wire functions. Sounds like your tuner has separate
switch settings for balanced and random wire. So I don't
know what that jumper statement is all about.

Cecil, for every question, there are any number of answers if you refashion the question. In this case the SWR was defined as !.7:1

You have created an all encompassing case from the original SWR of 1.7:1 No tuner needed. Under these conditions, the amount of reflected energy radiated approaches Ivory Soap.

OK. I think I understand. Assuming you are using the DirecTv dish, and
you want to replace the DTV horn with your own horn or dish feed, the
'phase center' of the DTV horn is about .25 lambda from the mouth of the
horn.

So, you place the phase center of your replacement feed at the same
point as the DTV horn's phase center.

Again, assuming you are using the DirecTv dish, neither the cantenna nor a patch antenna will provide ideal illumination for a DTV offset dish, which has an f/D of around .7

If you are OK with linear polarization (is the antenna for WiFi use?), I suspect a biquad would provide better illumination than a cantenna or a patch. Not that the latter two wouldn't work, it's just they aren't optimum for that f/D

Russ

The line he is refering to simply indicates which of the three terminals to
connect a balanced line to. It has nothing to do with a jumper.

Thank you, that's what I finally have figured out -- Murch made
several versions of their tuner; perhaps my copy of the instruction
manual refers to some other version, or maybe they just weren't clear
in what they were trying to say.

Thanks to all...

"Worst case."
Get it?
OF COURSE it isn't absorbed in the source.

One more time.
It was a WORST CASE calculation which placed an upper bound on the possible
loss
from operating into a 1.7:1 SWR as opposed to a 1:1 SWR.
In practice most of the power is eventually radiated.
sheesh!
H.

347. 80 Meter Horizontal Loop

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-05 16:57:03 UTC
From: GeorgeF <av8tor@licensed4funREMOVEBEFOREFLIGHT.com>
Message-ID: <z9Goe.14172$M36.12285@newsread1.news.atl.earthlink.net>
Source record: 75813

I put up an 80 meter full wave loop using about 280ï¿½ of #14 wire in almost a square. Each end of the loop was soldered to an SO-239 connector. Iï¿½m feeding the loop via RG-8 coax, about a 30ï¿½ run.

Using an MFJ Antenna Analyzer I canï¿½t find a nice low SWR point. The lowest I can find is at 2.5 MHz, the SWR at that point is still high at 3.4:1. In the 80 mtr band its 8:1 and in the 40 mtr band its 7:1.

My installation is far from ideal. First, the antenna for about ï¿½ the loop is at about 20ï¿½ high and the second half is about 15ï¿½ high. Next, in the center of the loop is the metal frame work for a screen-room over the swimming pool (50ï¿½ x 30ï¿½) which Iï¿½m sure interacts with the loop antenna to some degree. The screening is not metal however the frame work is.

Of course I can use my MFJ-949 tuner to get a low SWR on any band but by doing so am I loosing efficiency? I also notice that trying to tune the loop the tuner seems to be very touchy! I have noticed on 20 meters the loop received on average about 2 S-Units better than my 20 meter dipole. On 40 meters it receives almost 1 S-unit better than a 160ï¿½ randomwire. On 80 meters just slightly better than a 160ï¿½ randomwire. (all antennas Iï¿½m comparing are all at about 20ï¿½ high).

I would have started making the loop shorter to bring up the resonate frequency to 80 meters however Iï¿½m concerned as to why the lowest SWR I can find anywhere on the HF band is still over 3:1. Is it because the loop low to the ground (20ï¿½)? Or do I need a balum? 1:1 balum? 4:1 balum? Looking for any suggestions.

>almost a square.

Hi George,

That was certainly a good beginning, but questions abound as we
proceed.

>Each end of the loop

How many "ends" does a loop have? This is something akin to how many
sides to a circle.

>was soldered to an SO-239 connector.

One is enough, why two (or more, we still don't know how many ends
there are)?

This statement is enough to give pause. If there is more than one 239
inserted inline, it must of necessity break continuity of the loop.
This, then, means that you no longer have a loop, but rather a
fullwave dipole (presuming the loop has 2 ends).

> Iï¿½m feeding the loop via RG-8 coax, about a 30ï¿½ run.

You say nothing of choking the feedpoint, and given the symptoms that
you describe, this sounds like a major omission.

>In the 80 mtr band its 8:1 and in the 40 mtr band its 7:1.

Sounds like full wave dipoles (or even multiples). In other words,
consistent with previous descriptions.

>My installation is far from ideal.

No one here has it any better, but by degrees. If you can do better
by trying harder, fine, but if there's no way to get the antenna
higher, or to blow away the obstructions....

>Of course I can use my MFJ-949 tuner to get a low SWR on any band but by
>doing so am I loosing efficiency?

In trying to tune full wave dipoles? Could be, but being so close to
the dirt is probably lowering your antenna's wicked Z to something
easier to tune (your efficiency is already dominated by ground loss).

>I also notice that trying to tune the
>loop the tuner seems to be very touchy!

Lack of choking at the feed point - or - you are tuning an
anti-resonant antenna.

>I have noticed on 20 meters
>the loop received on average about 2 S-Units better than my 20 meter
>dipole. On 40 meters it receives almost 1 S-unit better than a 160ï¿½

>(all antennas Iï¿½m comparing are all at about 20ï¿½ high).

Now all your previous complaints sound like whining. Do you want a
tuned antenna, or a gain antenna?

BOTH!?

Tom,

Your particular cultural persuasion really doesn't really enter the discussion. It could be North American Red Indian. It sounds OK by me. I imagine most spoken languages admit to the use of 'and' anywhere within the spoken sentence. It is only natural that occasionally it should appear at the beginning of the written sentence.

I mentioned it to my friend Richard Clark because of the possibility, of so doing, it may cause irritation and thereby draw his attention to what I was waffling about. There are some silly academic objections to the use of 'And' at the beginning of a written sentence.

I was unaware of G.B.Shaw's ideas on how to conduct an irritating conversation. Thank you very much for drawing my attention to his remarks.

It is also pleasing to learn that some US citizens are familiar with the works, not just the plays, of GBS. His works have been turned by Hollywood into film - such as Ingrid Bergman as "Saint Joan". But GBS was not happy with the script. The political content of his play was distorted beyond recognition. But that's just Hollywood's pro-american propaganda for you.

Reg, G4FGQ

Reg:

Actually, both you guys are right on, "and" yes--I have always
thoroughly enjoyed British theatre and writers... I think their American
counterparts have always played a game of "catch up." Today "special
effects", sex and "painted blondes" and "action" replace the sorely
missed good strong actors and artists...

Dave

Do you know of a web site where the offset dish f/D is defined? I am
familiar with the conventional (feed at the center) parabolic reflector f/D.
My question relates to my wondering if the TV satellite dish is a parabola
with the horn feed offset away from the focal point.

Jerry

Hi Reg,

They should've stayed with GBS' pro-British propaganda? Or rather his
anti-British propaganda? What you offer sounds like a plagiarized
play program note.

Do ya think that oil prices will drop if we "start" to use Iraqi oil?

Tony seems to have PMS lately. It's OK, it's a passing (gas) phase...
He has had very bright moments. :^P (Haven't we all?)

About words of enlightenment - you need to find another newsgroup.

For dissertations, there are many PhD's here, or at least professed.

As far as oil goes, well, time will tell.

But, it's still only women that believe there's a difference between the
two.
So the people who know what they're doing with explosives,
always make it a point to only give Bush, Boeing, and Iraq Inc the good
explosives. Since they are retards like the Army, Navy & Air Force and
buy all their hammers at Walmart, who only buy triggers
at the moron club:

Doofus, Moron, Duh, and Microsoft, LTD.

Sounds like s successful installation. The tuner doesn't reduce efficiency - - it just tunes out reactance, leaving a resistive load for your rig to work with. Don't worry about SWR - - your radio doesn't worry about SWR (with the reactance tuned out) - - it sees stronger signals. You did good.

So you're trying to say that Livermore and the idiots at Pentagain
invented
something that even the North Korean miners club knows that the
Russians and Isaac Asimov invented.

Well it's good that rec.radio.amateur.antenna is on the thread.
Since even Hong Kong has stupid people, not only New York City.

George Bernard Shaw was a Fabian socialist. He believed that the aim
of most people of the society of his day was to become so wealthy as
to become economic parasites who didn't produce and didn't contribute.
He didn't like this, so he preached against it in his works. Since
producing wealthy parasites was what the business side of Hollywood
has always been about, it's no wonder they emasculated his script.

It wasn't a boast, it was an observation. You're a heartless fool.

I offer you no more enlightenment than you'd receive from an honest
assessment of yourself. But that is unlikely. Your ego, which you
displayed with that last paragraph of self-puffery, won't allow it.

Instead, I fully expect you to congratulate yourself on a self-awarded
victory.

Enjoy your party of one.

Tony

There is one SO-239 connector, there is one piece of wire which is 280' in lenght. On end of the wire is connected to the center pin of the SO-239 connector while the other end of the wire is connected to the braid side of the SO-239. Hope that clears up the configuration questions.

No I am not choking at the feed point. I was not told about a choke by other hams who mentioned I should give an 80 meter loop a try. Is a choke the same as a 1:1 balun? I was told (and found it also illistrated in print) that I could directly hook 50 ohm coax to the feedpoint. Tell me what I need to do to choke the feedpoint.

I had seen (believe it was one of the ARRL handbooks) that this antenna should have no SWR higher than 3:1, mine is 7+:1 so I think either I did something wrong or am missing something. Don't think I'm whining yet....

George

In TV broadcasting reflections from the antenna back to the transmitter will
be reflected by the transmitter to the antenna and the signal will be
rebroadcast albeit at somewhat less power. Then depending on the length of
transmission line the viewer may see ghosting.
In audio I don't know why and I have run my Collins 30S-1 into ladder line
with a 14 to SWR with no one except me knowing!

No, you don't get to play the part of wise-teacher grading my exam, it's
a painfully obvious ploy to assume a power dynamic that you are not
entitled to.

I called you the village idiot because of what you had to say about the
people of Iraq, and for following it up with that moronic "evil grin" in
brackets.

If you find it that painful to be insulted, then don't post idiotic
things.

Tony

Yes. Just turn the biquad so the one quad is 'on top' of the lower quad
and you will have horizonal polarization. The pattern looks pretty
symmetrical in both the E and H planes

Best of luck

George,
Since you have an MFJ Antenna Analyzer, is there some frequency, regardless
of the SWR, where the reactive part of the impedance goes to 0? I don't know
about horizontal loops, but vertical loops are not 50 Ohm antennas.

Common mode current could be upsetting your measurements as you
are feeding a balanced antenna with coax. Your loop seems to be
too long to resonate on the 75m band. By shortening it, you can
probably move that 3.4:1 point into the 75m band. But why not just
feed it with 450 ohm ladder-line through a balun at a tuner output
and alleviate most of your problems?

Wait a minute - back the truck up. I thought the Injuns didn't believe
in ownership of property. So if they didn't own it, how could anyone
steal it from them? Riddle me that.

Banks and gov'ts are like religious organizations, they tend to adopt
"bibles", I really never look for these institutions to be
"progressive." Frankly, if you offered up that bank code employed a lot
of Hebrew and Greek, I'd investigate first before claiming naught...

... heck, as far as bankers go--I'd not even be surprised if they were
the direct decedents of the original "money lenders in the temple."

Warmest regards,
John

> In practice most of the power is eventually radiated.

As Roy, W7EL, previously indicated:

Power reflection coefficient:
rho^2 = [(SWR-1)/(SWR+1)]^2 = 0.067 = Pref/Pfor

1-rho^2 = 0.933 = 93.3% forward power delivered to the load

93.3 watts is 0.3 dB down from 100 watts.

The log of the ratio of two SWRs doesn't seem to have much
meaning.

An ever better question would be, "Who will own it next (steal it next?)" We may thump our chests and cry our greatness--societies have done so before us, I think us fools if we believe we have discovered a society which will not crumble. Now, we may have--I keep an open mind--however, it will be the first if so... and there ARE enemies out there...

Thanks, I did the search, I didn't find the picture and I didn't pay
for the antenna.

I did see the mixed reviews. They are normal for about any antenna.

I need to know what kinds of radials, mounting etc. I need.

I just have the three sticks that screw into each other.

73 for now.

Same antenna - Solarcon acquired from Antron - from what I've read.
Its a decent 10 meter vertical.
Clamps onto a 1-1/4 pipe with u-bolt clamps and needs no radials - (but there's a kit)
and tunes to low swr with a couple of rings at the bottom.
I like it. Many hams don't like it because a CB-er used one.

Good Lord Roy, I thought you knew better.

If the match at the load is not perfect, energy is refleced back to the source, are you with me so far?

I can easily build a source that absorbs all the reflected power: A zero impedance source in series with a resistor that matches the transmission line impedance.

73
H.

Speaking of which - The National Geographic Channel recently
carried a program about another human species discovery on
Flores Island. They have been dubbed "Hobbets", averaged 3.5
ft. in height, were human, but a different species from us.
They appeared about 60,000 years ago and became extinct
about 15,000 years ago. Why would God do something like that?

Usually you would use ONE antenna for a repeater instead of 2 antennas
You need a duplexer (cavity filter) so the transmitter output won't get into
the receiver's input.
You have some research to do. It's not a simple 'normal' radio
installation.

>to become economic parasites who didn't produce and didn't contribute.
>He didn't like this, so he preached against it in his works. Since
>producing wealthy parasites was what the business side of Hollywood
>has always been about,

But how he reacted to:

> it's no wonder they emasculated his script.

was as GBS, a one man advertising agency for George Bernard Shaw. In that respect, GBS and Hollywood were on parallel tracks, even if they didn't converge. When GBS/Shaw fulminated, it was over other issues.

Basically the Fabian society's ethic was pie-in-the-sky economics that faded with Victoria. Shaw was infinitely more radical, and still more current today than ever with his up-front stories of sexual politics. Absolutely no one goes to a Shavian play to ponder the plight of masses burning the barricades before the classist society. Likewise, no one reads G.K. Chesterton and "The Man Who Was Thursday" when they can catch Father Brown instead. If you had your druthers, would you watch an edited version of "Man and Superman," or its interior play "Don Juan in Hell?"

Hollywood rebelled far more vigorously against ALL of Shaw's women protagonists than giving even the slightest thought about any economic theory. Your comment about Hollywood emasculating his scripts; in fact they pumped these scripts up with so much testosterone that "My Fair Lady" is a travesty of a woman submitting to and being redeemed by a man. It is this kind of cheesecake that sells, and selling movies is the ONLY thing Hollywood cares about.

If they thought they could sell communism (Warren Beatty's "Reds") then we would have been watching the life of Stalin in technicolor and surround-sound for the past 70 years. Anybody here ever see the movie "Greed?" This came from the pen of Frank Norris, one of the most

acidic writers against capitalism ever to come down the pike (and a contemporary of Shaw). Both of these movies were well made, by acclaimed directors and backed with wheelbarrows full of cash. To put it bluntly, neither of these examples drew crowds. Hollywood backs a winner and doesn't give a damn about ANY message as long as it doesn't interfere with selling popcorn.

>>meaning.

> It's called db, Cecil.

The IEEE Dictionary says the ratio of power, voltage, and
current can be expressed in dB. It specifically states
that dB can only be related to power ratios or to parameters
that are proportional to the square root of power ratios.

SWR1 = [SQRT(Pfor1)+SQRT(Pref1)]/[SQRT(Pfor1)-SQRT(Pref1)]

SWR2 = [SQRT(Pfor2)+SQRT(Pref2)]/[SQRT(Pfor2)-SQRT(Pref2)]

The ratio of two SWRs will not reduce to a power ratio or
to the square root of a power ratio.

> line impedance.
>

Let's see, I put a 100 volt zero impedance source in series with a 50 ohm resistor, connect that to a half wave transmission line terminated with 150 ohms. The current will be 100/200 = 0.5 amp, the power in the 150 ohm load is 37.5 watts, the power in the 50 ohm source resistor is 12.5 watts. The SWR is 3:1, the forward power is 50 watts, the reverse power is 12.5 watts. Sure enough, the power in the source resistor equals the reverse power. Good job. That sure must be the worst case, all right.

Just to check, I'll change the load resistor to 16.67 ohms. Now the current is 1.5 amps, the power in the 16.67 ohm load is 37.5 watts, and the power in the source resistor is 112.5 watts. The SWR is still 3:1, the forward power is 50 watts just like before, and the reverse power is 12.5 watts just like before. Hm. The reverse power is 12.5 watts, but the source resistor is now dissipating 112.5 watts. Must be worse than the worst case.

Well, shoot, maybe the source resistor dissipates all the reverse power *plus* some more power that comes from somewhere else. So let's try a 200 ohm load. Now the current is 0.4 amp, the power in the 200 ohm load resistor is 32 watts, and the power in the 50 ohm source resistor is 8 watts. The SWR is 4:1, the forward power is 50 watts, and the reverse power is 18 watts. Oops, the source resistor is only dissipating 8 watts but the reverse power is 18 watts. Not only isn't it dissipating all the reverse power, but it isn't even dissipating that extra power that came from somewhere else when we connected the 16.67 ohm resistor. Wonder where the other 10 watts of reverse power went?(*)

So using your simple criterion of a zero impedance source and resistor equal to the transmission line impedance, and by only changing the load resistance, we've got cases where:

-- The source resistor dissipation equals the reverse power
-- The source resistor dissipation is greater than the reverse power
-- The source resistor dissipation is less than the reverse power

And none of these will explain the loss figure you gave earlier.

Guess I don't know better after all.

Anyone who's interested can find more interesting cases in "Food for thought - Forward and Reverse Power.txt" at http://eznec.com/misc/food_for_thought/. And those who aren't interested, well, you're welcome to believe what you choose. Just don't look too closely at the evidence.

(*) Anybody fond of the notion that reverse power "goes" somewhere or gets dissipated in the source or re-reflected back needs to come to grips with this problem before building further on the flawed model of bouncing waves of flowing power.

Yes, SWR is a dimensionless quantity. dB is, as far as I know, defined only for power, voltage and current ratios, as the IEEE Dictionary implies. Since it's defined differently for power than for voltage or current (so that an increase or reduction in one quantity represents the same number of dB increase or decrease in the other), anyone using it for something else would have to clarify how it would be defined in that context.

As a follow up, found some excellent research on some balun testing for
just the use I mentioned, really good stuff:
http://www.dxing.info/equipment/impedance_transformer_bryant2.doc

John

"John Smith" <assemblywizard@gmail.com> wrote in message
news:LMame.163$0o.10684484@news.sisna.com...
I have a Grundig YB-500 (Yacht Boy 500) shortwave portable. I
frequently take it to remote locations with me and have enjoyed the
radio for years. It has a short pull up whip antenna, all I have done
in the past is to slingshot a long wire into a tree and use a clip lead
to attach it to the pull-up whip (no external ant connections on the
radio).

I was wondering what the impedance the collapsed whip would present, and
what sort or a balun/auto-transformer could be used between a longwire
(or other ant), gnd and the pull-up whip to improve reception...

... anyone ever done any experimenting or unique ideas?

Warmest regards,
John C. Smith

Hal:

I have heard others describe them (tv 75/300 baluns) as a normal, albeit small, toroid--I don't know, would have to get some and open 'em up--sounds to me like all sorts of designs could be being used....

But, if you look at the end of a binocular core, it does indeed have a outline much line a figure 8... however, all I have ever heard 'em called is binocular cores.... I have "duplicated" this design with two toroids, side by side before (and winding through "one side" of each independent core, touching at a "side" on each toroid--kinda hard to describe), and seemed to work for my purposes--but since I haven't seen anyone else doing it--so wouldn't recommend it at this point unless you like to experiment... have purchased binocular cores for use in mosfet linears before, they are out there...

Warmest regards,

Hi Hank,

That would pretty much reveal the SWR if we knew, wouldn't it? If
"somewhat less power" was in 1.2:1 ratio, we wouldn't care so much,
but how would the viewer feel about such service?

>Then depending on the length of
>transmission line the viewer may see ghosting.

I think we, or another correspondent and I have dealt with that at one
time. At the time I believe it was called "fringing," not "ghosts."
The difference being that what were called ghosts at the dawn of the
TV era were separated by fractions of an inch rather than fractions of
a mm. As such, ghosts couldn't have been originated by anything
shorter than mile length transmission lines that were poorly
terminated at both ends. Instead, ghosts were actually transmission
path length differentials in a multipath situation.

>In audio I don't know why and I have run my Collins 30S-1 into ladder line
>with a 14 to SWR with no one except me knowing!

Well, if this is meant to be analogous to fringing/ghosting, I suppose
its because a microsecond blur at AF is entirely inaudible. Or are we
speaking of SSTV? However, this begs the question, How did you know?
All the Collins equipment I taught at school didn't come with a SWR
meter. It was wholly unnecessary if you performed the standard
tune-up. Matter of fact, back then the only SWR meter I saw was for
Ham gear. The finals' tank performed every function of matching as
any tuner.

However, with the KWT-6, we did use an external tuner, 180-V1
(although I may have this mixed up with another model), for coax
feedlines. This was more for its automatic feature where the
transmitter could be tuned up with a 50 Ohm load, and the automatic
tuner simply did the job of presenting it with the transformed load.

However, returning to the point of a transmitter rereflecting a
reflection; I know the bare KWT-6 into ladder line employs its tank to
protect its final tubes. Without that safeguard, I have seen plates
melt - something no one here wants to call dissipation lest it be

evidence of an internal resistance. The bare tubes with their native very hi Z would rereflect like nothing else - and this begs the observation - how could you get original any power out of them, past the tremendous mismatch? The tuner/final tank comes back into the equation, and rereflection goes out the window as a property of the transmitter and returns to the domain of matching.

If anyone wants to constrain the entire crusade of the rereflecting transmitter to the tube set feeding ladder line - then feel free to do so. However, I don't think I've ever seen a mobile tube rig feeding ladder line - no doubt one day I will. We will probably talk about efficiency. :-)

Cecil, not a very surprising statement.
There's nothing which is 100% efficient.

What is the typical efficiency of a typical tuner with a typical
antenna.
Does it differ significantly from 100% ?
Yes or no?

Reg.

Well, at the risk of David going into conflict with the Goliaths of the newsgroups, I would reckon that a tuner (matcher ?) must be a pretty efficient device as it doesn't get very warm from wasting energy as heat - or perhaps my aerials are a reasonably good match and the tuner isn't doing any / much work. Also a tuner, I would suggest, is a fairly useful bit of kit in that it enables the transmitter to see the sort of load it wants to and allows it to deliver more power to the antenna system without the internal protection devices limiting the power it produces (to avoid self destruction) even if not all arrives at the antenna.......

Is this a fairly correct understanding of what is going on, Reg / Cecil ?

Nick

However, I don't think I've ever seen a mobile tube rig feeding
ladder line - no doubt one day I will. We will probably talk about
efficiency. :-)

It was done in 1936.
http://web.wt.net/~nm5k/mobile36.jpg
Cover pix from a 1936 QST...Forgot
what month...
But I still think I prefer coax...
Their "ladder line" looked to be a twisted wire feeder.
The call on that vehicle was W9MSY...
With the short feedline run on a mobile,
even coax is pretty low loss...
I never used an SWR meter when I was a
novice...I had an old viking valiant that would
tune nearly anything...You didn't need a meter...
You just loaded it up to full plate current and went
with it...My TS 830 is like that to a lesser extent..
If it loads within the loading range, it's good nuff...
No point in even putting a meter on it...Adding a
tuner, would just add some loss...MK

> Are those small 300/75 ohm tv baluns. voltage or current type?

Hello, and these broadband 4:1 (impedance ratio) baluns most often are voltage type using two transformers. At the lower end of the operating frequency band the balun appears as a 4:1 autotransformer while at higher frequencies the transformer windings appear as transmission lines (ideally each line would have a Zo of 150 ohms). FWIW, the broadband operation of these types of devices were initially described in detail in C.L Ruthroff's 1959 IRE paper, "Some Broadband RF Transformers." Sincerely,

> bouncing waves of flowing power.

Roy, none of my textbook authors think the reflection model
is flawed. Walter Johnson goes so far as to assert that there
is a Poynting (Power Flow Vector) for forward power and a
separate Poynting Vector for reflected power. The sum of those
two Power Flow Vectors is the net Poynting Vector.

Here's my earlier thought example again.

100w----one second long lossless feedline----load, rho=0.707

SWR = (1+rho)/(1-rho) = 5.828:1
Source is delivering 100 watts (joules/sec)
Forward power is 200 watts (joules/sec)
Reflected power is 100 watts (joules/sec)
Load is absorbing 100 watts (joules/sec)

It can easily be shown that 300 joules of energy have been
generated that have not been delivered to the load, i.e.
those 300 joules of energy are stored in the feedline.
The 300 joules of energy are stored in RF waves which
cannot stand still and necessarily travel at the speed of
light. TV ghosting can be used to prove that the reflected
energy actually makes a round trip to the load and back.
A TDR will indicate the same thing.

Choosing to use a net energy shortcut doesn't negate the
laws of physics.

Some ARRL publication said the losses in a tuner average about
0.5 dB. If true, a tuner indeed reduces efficiency by about 12%.

==================================

Nick, your response indicates a 'perfect' understanding of what goes
on inside tuner boxes. If it runs cold or cool with 100 watts there's
```

nothing to worry about.

Most Guru's over-exaggerate the importance of tuner losses. But in a practical case they never state what the efficiency actually is. Such omissions illustrate their ignorance of the subject.

From the frequency of occurrence at which 'tuner loss' appears in these columns, novices and even experienced amateurs can gain the frightening impression that tuner loss is the most serious loss in the system and is to be avoided at all costs, even to the extent of dispensing with the tuner.

In answer to my own question, the efficiency of a typical tuner when used with a typical antenna does not differ significantly from 100 percent. Even if it is as poor as 90% this corresponds to an undetectable loss in signal strength of 0.5dB or 1/13 of an S-unit. Less than the thickness of the S-meter needle. So forget it.

Reg, G4FGQ

Only the 'quality' ones. I've seen too many that were simply
resistor bridges. More like a 6dB insertion loss per leg than
the 'ideal' 3dB loss in a quality transformer-built version.

Sorry, I misquoted there. Walter Johnson doesn't say anything
about Poynting Vectors. The above is from: "Fields and Waves ..."
by Ramo, Whinnery, and Van Duzer, page 350, where they assert:

Pz-/Pz+ = |rho|^2

The reflected power Poynting Vector divided by the forward
power Poynting Vector equals the power reflection coefficient.

Cecil,

I will presume that your reference to Walter Johnson is with regard to his book, "Transmission Lines and Networks", published in 1950.

I have been unable to find any mention of Poynting Vectors or Power Flow Vectors in my copy.

Would you be so kind as to identify the page number(s) describing these concepts?

73,
Gene

My point was that some languages have different underpinnings than others and these help define the boundaries of the languages. No amount of #defines will allow a C compiler to provide subroutines with full access to the main program symbol table. (Making all variables external (in the C program) could accomplish this, but would be unreasonable for many other reasons.) There really are differences in languages beyond the obvious syntax differences.

I tend to measure languages (and programmers) by their maintainability, measured in decades. Possibly one my most important business actions was helping kill application development in APL.

Of course, IMHO, anything worth writing is done is assembly language --- but that is a different debate.

Bill:

Too be perfectly frank with you, all who I have ever seen argue syntax
simply can't program--that doesn't mean they don't think they can...
If you find a programmer who is having difficulty maintaining C, I think
you will find he/she has difficulty maintaining any syntax...
C can simply do all of the other languages combined--at its first
creation by dennis ritchie it was "all powerful." Since that time many
have posed arguments of why it should be limited--they even go to the
extreme of attempting to hide these attacks on the language in
"standards", so far all these attempts have failed--thank gawd...

Warmest regards,
John

Gene,
My next posting admitted my senility. I was quoting Ramo & Whinnery,
not Walter Johnson. In "Fields and Waves in Communication Electronics",
page 325, an equation is given for Pz+, "The Poynting vector for the
positive traveling wave ...". It continues: "Similarly, the Poynting
vector for the negatively traveling wave is always in the negative 'z'
direction except when it is zero."

On page 350 it gives the ratio of the forward Poynting vector to the
rearward Poynting vector as the power reflection coefficient. Sorry
for my faulty memory.

Code reviews are not absolutes. The notion is to have many eyes staring
at something so that, as a group, they can spot problems and pitfalls.
Sometimes we aren't even talking about errors. It's important in a
large product to organize components and interfaces and such in a
sensible manner, and sometimes someone will point out where you can
refactor or where you are "reaching around" to a software component you
shouldn't be accessing directly. Code reviews can take many forms, as
well. Most of the time it is just water-cooler talk when working on a
problem, and then a reviewer or two before changes are committed.

Bigger projects almost require a weekly sit-down with dead-tree version
of the code in front of you.

There will always be errors in software. The idea is to use the tools
and protocols appropriate for the task and application to help minimize
the errors and to control the effect of the errors over time.

The enterprise software business depends to some extent on something called "SCM" (Source Code Management) or "ALM" (Application Lifecycle Management) to manage change to critical business systems over time. The "black box" method you talk about is fine, but only as long as there are internal processes guiding decisions about how code is changed for any reason.

Failure to do so will result, eventually, in tears and recrimination. I've seen it and I've lived it.

Generally, any company that makes software knows that that software is it's greatest and most important asset. Managing that asset is what what I've been driving at, and what (I think) "kashe" was hinting at, as well.

Really, for any large software project there is one simple rule: Every time a developer makes significant changes without some sort of code review, God kills a kitten.

Reliability of computer programs is the most important attribute.

The concept of MTBF, Mean Time Between Failures, can be applied to
software.

Does anyone disagree?

Roy, I have had an article for review into QEX for more than two
months that explains what is missing from your analysis. Unfortunately,
I have not heard a word from QEX since I submitted the article.

So I will introduce a concept new to the field of RF but completely
understood in the field of optics. I actually introduced this concept
three years ago in discussions on r.r.a.a with Dr. Best but I was
apparently unable to convey the concept.

If I ask you what things can cause 100% reflection, I assume you would
list three things: 1. A short-circuit, 2. An open-circuit, and
3. A pure reactance. And that is indeed true for loads upon which a
single wave is incident.

But the field of optics recognizes an additional thing that can cause
100% reflection and that's wave cancellation. If two coherent EM waves
are traveling the same path in the same direction in a transmission
line and they are 180 degrees out of phase, the waves will cancel and
the energy components in the two waves, which must be conserved, will
be 100% reflected in the opposite direction. The following two optics
web pages verify that fact for EM waves: (near the bottom of the pages)

http://www.mellesgriot.com/products/optics/oc_2_1.htm

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index
.html

What is happening in your "food for thought" assertions is that you
are neglecting the ability of the phenomenon of wave cancellation to
cause 100% reflection of the energy components in the two canceled
waves, something that is well understood in the field of optics.
Dr. Best also neglected to take interference energy into account in
his QEX article on transmission lines.

"Optics", by Hecht asserts that for every incidence of constructive interference there must be an equal magnitude of destructive interference to satisfy the conservation of energy principle. (That is unless the source itself is capable of delivering extra power.) By the same token, if the source doesn't absorb constructive interference energy, it must go somewhere else. In a transmission line with only two directions, there is only one other way it can possibly go and it becomes a reflection or a re-reflection.

What is happening in your "food for thought" examples is that destructive interference/wave cancellation between the forward wave and reflected wave is occurring at your source. That wave cancellation event is feeding constructive interference energy back into the feedline which joins the forward wave energy. Your discussions ignore the effect of interference energy which must necessarily be conserved.

Your argument goes something like this: I am ignoring the constructive/destructive interference energy involved in wave cancellation. Therefore, it never existed in the first place. That's a petitio principii type of argument.

Hi Mark,

Hmmm, the picture's kinda small, and the line looks like coax - or
maybe close ladder line. I will take your word for it as it makes my
track record for accuracy complete. :-)

Well, almost complete. Is the guy holding his pinkie to the radiator
measuring efficiency?

As a sidebar, the police were working 160M mobile back then too.
Seems coax was hardly an off-the-shelf item. Think they used ladder
line too? More probably direct feed.

A million programmers can look at source and miss a very simple error, a million professional computer users can use the application and never discover the error in code--let one computer illiterate dummy have the keyboard and an immediate crash occurs...

You keep large data files of previous errors which are known and simulate real world entry of such "garbage" to the application, in debugging you literally toss everything but the kitchen sink (well, maybe that too) at the development project from tons of "error generating data files"... you exercise its dynamically created buffers and constructs with endless streams of junk, a lot randomized... you attempt everyway possible to break the running of the application--as time goes by you get better at this testing... if it passes all this on multiple high speed machines testing for endless hours/days--you then release it for beta testing--if you have done the testing well, there will be few reports of errors from beta testers... then the computer illiterates get their turn...

Warmest regards,

Not easy if t < 2 sec. :-)

> The 300 joules of energy are stored in RF waves which
> cannot stand still and necessarily travel at the speed of
> light.

It's ironic that the first paramater cited in the problem starts with an
'S'. :-)

> TV ghosting can be used to prove that the reflected
> energy actually makes a round trip to the load and back.
> A TDR will indicate the same thing.

If either source were monochromatic, I bet I could come up with an
example where the surfaces reflect no energy. :-)

> Choosing to use a net energy shortcut doesn't negate the
> laws of physics.

Particular when characterized as a matter of opinion, it can be like
having a religious discussion.

Cecil,

You can't be serious!

This is basic stuff found in virtually any intermediate level E&M textbook.

The treatment is generally the same; start with the field equations describing the waves, add the material conditions and the boundary conditions, plug and crank. The answers pop right out. No need to invoke any magic incantations about interfering waves or wave cancellation. The interference is the result of the analysis, not the cause.

In the classical case, there is absolutely no difference in behavior between "RF" and "optical". The material properties for every situation can vary, but the physical principles do not.

Sooo, rather than introducing a new concept, you are perhaps the last person to finally understand the old one.

Let me refer to you to this link:

http://users.triconet.org/wesandlinda/ladder.htm

and suggest that you also follow the imbedded link to my letter to
Dean.

There you will find an analysis if what tuner losses can be.

But let's also answer this issue of "It doesn't get hot, so it must
not be lossy."

First let's say that, unless the op is a real blabbermouth, the
transmit duty cycle will be 50%. Transmit half the time, listen half
the time.

If the op is on CW then the duty cycle of the transmit cycle is ~44%.
(The standard word "PARIS" sent repeatedly with 1:3:7 spacing. So for
CW operation, the overall duty cycle is .5 * .44 = 22%.

On SSB it's more complicated. Without speech processing, the peak to average ratio is variously given, but 14:1 (11.5 dB) is typical. Most rigs have some form of speech compression or clipping these days (most used to excess). Really effective clippers, (ahem)

http://users.triconet.org/wesandlinda/s_proc.pdf

can improve this quite a bit so let's say that it's 6 dB. So the average power is 6 dB below the peak or 25% of the peak. Our overall duty cycle is .5 * .25 = 12.5%

Of course the digital modes and FM are full carrier so the duty cycle is 50%. Not many using FM on hf where tuners are the norm, the PSK guys pride themselves on QRP, which leaves only the special case RTTY contesters running full power.

So back to the guy running 100 W CW through a tuner driving a ladder line fed antenna. If his tuner burns up half of the power will it get hot? Are 11 W (22% of 50) going to smoke most components? What if the tuner loss is 6 dB? The average power dissipation climbs to a whopping 16.5 W. (22% of 75) Is this a big thermal management issue?

Certainly, KW rigs running RTTY are going to be a bigger concern, but the tuners (and component parts) are commensurately bigger and can dissipate more power without "getting hot".

<kolesnik@sbcglobal.net> wrote:

>Please tell me more about melting the finals and a bit more explanation of
>what was happening?

Hi Hank,

Direct observation offered a glowing plasma between the filament and
the plate. It was football shaped rather than beam-like or an
amorphous cloud. One point of the football touched the cherry red
plate. Following a quick power-down, that point on the plate did not
exist anymore as there was a hole. Couldn't really tell, but no doubt
the grid suffered just as much in its own way.

I suppose plates have become more robust over the years since that
amazing demonstration. I helped fix one friend's Amp when it failed
along with his antenna (or t'other way round as the chain of causality
would suggest). His Amp simply quit working suddenly during bad
weather. Fuses checked - OK. No interlocks were open - OK. The tube
looked good at a glance - OK. HV Supply looked good - OK. The
filaments failed to light up - odd, but consistent. Time to crack
open the case. Pulled the tube and measured its filament continuity -
OK. Measured filament supply - OK. Things were really getting
strange. Time to bust the chassis open and really look. There on the
baseplate were several small pools of solder in a circular pattern -
how odd. Close scrutiny of connections revealed bright and soldered
wires to everything - OK. Time to look at the tube again. Every pin
was solder free - that was on the chassis base plate. [dirge played
here] The filaments' wires were making enough contact to measure
continuity, but no where enough to support real power.

In other tubes I've seen the heat become so extreme that the glass
envelope slumped into the vacuum and enclosed the plate structure like
taffy. This didn't even crack the glass (or it had simply re-fused).
Tube still worked afterwards though (so I would suppose the glass
never cracked). One occasion was actually due to a bias problem
created when the cathode load shorted. Lack of bias protection sent
the circuit into massive conduction. Of course the short came about
because of an initial excessive conduction (surprising in its own
right because the common failure mode is to open).

I've also seen stressed thyratrons so mismatched that they filled the
workspace with their purple glow like a floodlight. Thankfully fuses
work as I did not want to be near that final testimony.

Now, that was the short list of Bottle failures. I have another list of melted state failures too, but their evidence is usually better hidden and less dramatic - heat sinking generally spreads the risk, so to speak. And speaking of heat sinks, I've drawn a number of blisters from those that normally only warmed my hand. Note there should be emphasis on normally warm and the obvious contradiction with blisters.

Experience with failure has strongly correlated with heat and mismatch. Heat was born by resistance. Resistance is part of life and amplifiers. Heat comes in two forms. Slow-like, which is generally current based; and sudden, which is generally voltage based. I've felt along heatsinks immediately following failure that were as cool/tepid as usual, or ominously cooler! The sudden heat of arc-over in silicon can destroy just as effectively as the long slow broil of a plate turning to slag.

Every mismatch in the Amateur experience is a probablistic spin of the wheel of misfortune. Sometimes the wheel stops on the slow bake that aborbs into heatsinks and you notice unusual smell, or your fan running on too long - Quick! do something, and you survive. Other times there's the snap of finality. Both of these examples are for those with keen senses, and often failure comes as a whimper.

Most suffers usually discover what matching is for, even if they don't know how it works.

Jim:

Well, I have found terminology interesting. And, depends on whose you use, there is ARRL of course, then there are a bunch of in-house tech docs from industry.

Take what I have been accustomed to calling a 1/2 wave monopole--for example: on 10 meters, it is about a 16 foot metal length and end fed. An EFHWA. Most frequently fed through an L-Match or 1/4 wave matching section--sometimes uniquely though an unun.

However, if you attempt to feed it in the middle, it suddenly becomes a dipole, the equiv of two 8 ft-1/4 wave monopoles connected at there bases, and would take a unique feed I am not familiar with, as each 1/4 wave section would need be fed out of phase--and this would be difficult with the impedance so close to the feedline (coax in this case) and having the 1/4 monopoles connected (notice, I didn't say impossible! <grin>.)

Spilt the 1/2 monopole and center feed it and it becomes two 1/4 wave monopoles (commonly referred to as a 1/2 wave dipole) and can be center fed with convention means quite easily, as a dipole (indeed, many feed them directly from coax--the more picky through a isolation balun or 1/4 wave section.)

However, two 1/2 monopoles, connected at their bases (actually a 1 wave length single element) begins to accept center feeding with quite conventional means (ant feed point is high impedance), although in ARRL literature this would be referred to as 1 wave dipole, still it could be modeled as two 1/2 wave monopoles being fed out of phase.

All I am concentrating on is the EFHWA (and, if setup right requires no counterpoise), and various means of feeding it, modifications and experiments...

If you can provide me with a reference that says, wave cancellation can cause reflection of the canceled waves, I will be eternally grateful. I have been able to find references that imply such for light waves, but I have not found one that comes right out and says it for either light waves or RF waves.

I agree with you 100%. I had this "basic stuff" taught to me at Texas A&M half a century ago. But Roy's "food for thought" stuff completely ignores exactly that "basic stuff" concerning constructive/destructive interference. Nowhere in his arguments is "interference" even mentioned. I expect him to respond that interference is irrelevant. Dr. Best went so far as to deny that interference is necessary for a Z0-match to occur in a system with reflections. That was around May/June 2001 on this very newsgroup for anyone who wants to Google it.

I have been fighting this battle for three years on this newsgroup. Now you say it's "basic stuff". I've agreed for three years, but where have you been all this time?

Some people have forgotten what they learned in college. Their net/steady-state shortcuts have become reality and scrambled their brains. You are obviously not one of the people at whom I aimed my remarks. I am glad to see that not everyone has been seduced into thinking that interference is irrelevant.

> In the classical case, there is absolutely no difference in behavior

I know that. You know that. We are on the same side. Now convince the RF gurus of that. Roy calculated the net power at the source and assumed from that figure that there was not enough energy available to support the energy in reflected waves.

> Sooo, rather than introducing a new concept, you are perhaps the last
> person to finally understand the old one.

No, not the last one. What you say is exactly what is wrong with
Roy's arguments that reflected energy doesn't flow from the load
back toward the source. I am NOT introducing a new concept. I am
introducing a new (or forgotten) concept to some of the RF gurus
on this newsgroup. I am (re)introducing destructive/constructive
interference concepts to Roy, Dr. Best, and others.

Jerry-

I understand there is a class of unsymmetric antenna where the feed is
actually at the focal point, but the reflecting surface is only a side
section of the whole parabola. Although it is physically "offset", it
functions as a parabolic antenna.

I could be wrong, but here's what I was getting at. You should be able to vary the feedpoint impedance, where ever the feedpoint happens to be (in this case, the end), by varying the distance between the attachment points of the two conductors of the feedline. The closer they are together, naturally, the lower the impedance. It should be possible to find a match in this way. Part B would be to keep the feedline from trying to radiate.

Hi Reg,

Of course. MTBF is more apropos to linear systems. For digital
hardware, failure is dominated by either infant mortality, or old age.
Very rarely is there a problem in between.

As for software, any notion of time is utterly ridiculous. Any
operation that successfully performed once will ALWAYS perform
identically every time again. There is no such thing as a time
between failures such that the software will be reliable in between.
That would be spooky beyond superstition.

The best that you can expect from software is that if it is simple
enough, you can trust it to do the same thing again - a Brit by the
name of Alan Turing proved this some 60 years ago. Turing also
offered there is no way to guarantee a program will work, unless you
are willing to watch it for as long as it was running. For a quick
reference, google Turing and Enigma machine.

I don't see anything on those web pages that's outside the concept of the ordinary interference of waves, i.e., that they add and subtract where they occupy the same space. I don't at all see the concept of a wave of flowing average energy being bounced back or about by another wave, which is what you're proposing as you have many times in the past. But then, many people find miracles when I see only coincidence, so I'm a bit deficient in that regard.

This topic has been previously discussed beyond a tedious degree in this newsgroup; anyone interested can find it via groups.google.com. I don't have anything to add to it, with the exception of this question which is relevant to the topic:

Does your analysis produce the result of 2.3 dB loss claimed by H. for a 1.7:1 SWR?

Best luck with your QEX article. I look forward to reading it.

I'm afraid that your difficulty in finding a reference is simply due to its not being so.

If it is indeed so, it appears that your forthcoming QEX article will be a seminal work, as the first published work to explicitly state that this phenomenon indeed happens (outside of countless newsgroup postings to that effect). Assuming you understand the physics which causes it to happen, I'd think that a professional publication would be a much more appropriate forum than QEX for such an important work. Have you tried any of the IEEE publications?

I do. It's a much too simplistic concept. "Failure" can be a bug which requires a second mouse click when only one should be needed, one which causes a critical output value to be wrong by an amount that's serious but not obvious, one which causes a plane to crash or a bridge to fall, or anywhere in a continuum between them. It's shortsighted and can be badly misleading to lump these vastly different flaws together into a single quantity "failure".

Even if you did adopt this terribly simplified model of failure, the mean time (presumably in user-hours for typical desktop computer software) between "failures" depends very heavily on the user and how he uses the sofware.

While it might be a useful concept for some small class of programs which perform a small set of tasks, I'd consider any stated number for MTBF for most typical desktop programs as simply a fabrication of the marketing department. It could be made to be pretty much whatever they choose it to be.

> Regards
>
The short answer is yes. But such a connection isn't usually infinitesimally short, so current will flow along the path and the path will become part of the antenna and radiate.

An antenna is a circuit, and like any circuit it has two terminals. Our calling one of these "ground" doesn't give it any special or magical properties -- it's simply one of the two connections. However much current flows into one of the antenna terminals must flow out of the other. If we connect, for example, a piece of coax from a transmitter to an antenna and connect only the center conductor to the antenna, then the outside of the coax becomes the other half of the antenna. If one amp flows into the antenna, one amp flows along the outside of the coax shield. This would be the case for the microstrip antenna you describe, if you're really describing it accurately.

Follow the current from the "hot" side of the transmitter to the feedline, along the feedline to the "antenna", back from the other terminal of the "antenna" to the "ground" side of the transmitter. Anywhere the current is flowing right beside an equal current going in the other direction (to simplify a bit), like it does on the inside of a coaxial cable, there won't be any significant radiation. But anywhere a current is flowing where there isn't a very nearby, opposite current, the conductor is actually part of the antenna and will radiate.

Let's put this an easier way, how many of you have a low pass filter in line. Most manufacturers claim a .25dB or less insertion loss. These filters consist of a boat load of coils and caps.

A tuner normally has 2 varible caps and a single silver plated coil.

While any device indeed has loss, here we are picking fly crap out of pepper.

If I'm neglecting an important phenomenon, then surely some of my numerical results showing voltages, currents, forward, reverse, and total powers, and power dissipation must be incorrect. And an experiment can be set up to demonstrate their incorrectness and the validity of the alleged phenomenon.

I'd appreciate it very much if you or anyone else who finds any incorrect results in that series of essays, or anything else I've written or posted, bring it to my attention so it can be corrected.

This only addresses "bugs." Everyone ships code with bugs we know about and bugs we don't. Since QA is typically the most expensive part (in terms of man-hours) we might want to minimize bugs as much as possible in the unit-testing phase.

However, this does not address the issues of component scope or design, or refactoring, both of which are critical to maintaining a large project over any serious length of time.

Bugs are the easy part, and they are not strictly why one should have code reviews of some nature.

> You keep large data files of previous errors which are known and

Again, test cases are important, as they allow us to test for things we already know about, and help keep changes from introducing regressions. This is, however, only a tiny part of what good software management practices help achieve.

Doing a modest amount of testing from the three classic QA contexts is important:

1. 12-yr old hacker, who wants to break your app for a laugh.
2. Timid 80-yr old grandmother who may not comprehend your UI in any typical manner, nor understand the underlying system enough to figure out how to make your app work.
3. A monkey, who throws garbage and feces at your UI, occasionally powering off the machine in a fit of anger.

At some point all the QA you want is not enough. There will always be bugs that escape QA detection, and code reviews will likely not catch those either.

Well, Gene says it is really basic stuff (not worthy of a second
thought). Which is it? - Not worthy of a second thought or seminal
work?

Nope, I haven't. I've retired from being a pro. Now I am just
an amateur.

When two coherent waves traveling in the same path and direction are
180 degrees out of phase, they disappear from existence in that
original direction of travel, i.e. they undergo wave cancellation.
When they are confined to a transmission line with only two directions,
the flow of energy in the original direction ceases. There is no other
choice but for the energy in the two cancelled waves to be conserved
and to reverse direction and start flowing in the opposite direction.
That, my friend, is a reflection. How can you possibly believe that
the energy in cancelled waves is not conserved?

So to your list of shorts, opens, and pure reactances being able to
cause 100% reflection, you can add wave cancellation. Note that wave
cancellation cannot happen at a single load with a single incident

wave. It can only happen at points where there are waves flowing
in opposite directions, e.g. match points on transmission lines with
reflections and at sources subjected to reflections.

Please don't argue that you have never seen such. Anyone who has
looked at an oil film on water has witnessed reflections caused
by interference and wave cancellation.

Unfortunately, simply counting the number of coils and capacitors isn't even an approximate way to judge loss. What counts, mainly, is how much current is flowing in those inductors and how large their wire is (and, if the capacitors have other than air dielectric, perhaps how much voltage is across the capacitors)(*). If you do an analysis of a tuner, you'll find that for a given applied power, the inductor current can vary a huge amount depending on the load impedance. Consequently, the loss can vary a greatly.

Lowpass filters are invariably specified when in a circuit with a fixed, specified impedance load. It's not hard at all to design a lowpass filter which has low loss under that condition. Likewise, it's not hard to design a matching network (tuner) which has low loss when the load isn't too far away from 50 ohms resistive. The trick is to maintain reasonable loss when the impedance transformation is extreme.

Actually, the concept is a little different for software. It's called Mean Time To Failure (MTTF) rather than MTBF. The difference is because the bug that causes the failure is already there waiting for the right conditions to show itself rather than being caused by something breaking after having been placed into service. Toward the end of it's operational life the MTTF for IBM's OS360 operating system was on the order of 3000 years. That means that if there were 3000 computer systems using it and they were in operation 24 hours a day seven days a week, a new bug was being detected only once a year.

I don't think software reliability is valued very much these days. For those selling software, time to market seems to be much more important than reliability. For those buying it, price seems to be more important. That's why we have to buy additional antivirus and spy detecting software to protect our computers. A whole new software industry has grown up because we don't require reliability in the software we use.

No, they are not incorrect. They are net values and, as
such, are simply incomplete. Dr. Best had the same problem
in his article which was accurate but incomplete. The
problem with incomplete information is that erroneous
conclusions are likely to occur. In addition to a closed
mind, that's your present problem and Dr. Best's problem
with his QEX article.

Valid data being incomplete can sometimes be just as bad
or worse than data being wrong.

Cecil,

I do not expect that the reference you seek can be found.

There is no need to invoke interference or wave cancellation to explain anything, and it is unlikely there is any mathematical formulation that uses interference as one of the input variables.

It is totally unnecessary. Maxwell's equations contain everything needed to accurately describe electromagnetic interactions, including wave reflections, cancellations, and interference.

Any serious treatment of the subject of electromagnetic interactions begins with the field equations, not with the resulting interference. The sort of description found on the Melles-Griot web site and on their CD-ROM is a handwaving, but comforting, description meant for general understanding, not for detailed analysis.

> go? If it goes to the load and back, why does it reflect off the source
> resistor?

I have read the third example, which is NOT steady-state,
and I don't understand the question. Give me some steady-
state values and I will discuss it.

****
However, a reflected wave approaching a source resistor doesn't
encounter the source resistor as an isolated load. The source
voltage superposes with the reflected voltage at that point
which may, in reality, actually turn out to be an impedance
discontinuity.
****

Quoting Ramo and Whinnery: "It must be emphasized, as in any
Thevenin equivalent cirsuit, that the equivalent circuit was
derived to tell what happens in the ***LOAD*** under different
load conditions, and significance cannot be automatically
attached to a calculation of power loss in the internal
impedance of the equivalent circuit."

We have been speaking strictly software, if hardware changes are possible a "driver model" must be adopted, core code should always be able to remain static and functioning independently in regards to these hardware changes--in a perfect world...

With PC's movement between operating systems can be a bit more difficult--movement to linux will generally be expensive in a windows dominated world (most remaining mainframes have well developed transitional models and is cheaply implemented), however since the client obtained the OS for low cost (or no cost) they should be more than able to shoulder the related expenses...

While microsoft has indeed adopted the 80 year old grandmother model you have mentioned in your post--I always recommend ignoring her, some of us prefer to always plan for the 15 year old hacker who gets lucky, and the gorilla...

... your final protection always rests in insurance against claims made by those who have been harmed in using your code/application/utility/etc--and the contract/disclaimer for such--which, as everyone knows, if you make it long enough will never get read, so by all means, make them responsible for everything in its text--personally, I am always tempted to make them responsible for acts of God which may occur while they are using the software--guess that is why they don't let me write them... <grin>

Warmest regards,
John

But there is, Gene. It's the only way to correct the present misinformation and old wives' tales being promoted on this newsgroup. It is obvious that the r.r.a.a poster who understands the role that interference plays in the conservation of RF energy is very rare.

There is a conspiracy to keep this information from surfacing - "Nothing new", "no need", "irrelevant", "who cares?" Why are you guys afraid to discuss the technical details?

This should be an easy question to answer. If two coherent waves of 50 joules/sec each, are traveling in the same path in the same direction and are 180 degrees out of phase, they cancel in that direction of travel. What happens to their 50+50 joules/sec? Hint: energy doesn't cancel and there are only two possible directions. Can you spell R-E-F-L-E-C-T-I-O-N?

It most certainly is steady state, as are the other two examples. Perhaps I wasn't clear in saying I was referring to my recent posting. Here it is again:

[The setup is a 100 volt zero impedance voltage source in series with a 50 ohm resistor driving a half wavelength of 50 ohm transmission line.]

Well, shoot, maybe the source resistor dissipates all the reverse power *plus* some more power that comes from somewhere else. So let's try a 200 ohm load. Now the current is 0.4 amp, the power in the 200 ohm load resistor is 32 watts, and the power in the 50 ohm source resistor is 8 watts. The SWR is 4:1, the forward power is 50 watts, and the reverse power is 18 watts. Oops, the source resistor is only dissipating 8 watts but the reverse power is 18 watts. Not only isn't it dissipating all the reverse power, but it isn't even dissipating that extra power that came from somewhere else when we connected the 16.67 ohm resistor. Wonder where the other 10 watts of reverse power went?

Must have bounced off the forward wave, then? If so, did it bounce only when it reached the source, and not all along the line? Why? How much of it bounced back at the load and why? Can you show me how you calculate the various source resistor dissipations for this and the other two examples using your bouncing average power model?

I'd also welcome H.'s comments on this.

Richard

I've seen 3-500Z where the solder had melted out of the filament pins.

I have some 811 from my 30L-1 that have holes in the plates, they still work quite well. It's been 15 years since I recall finding the holes in the plate sides and replacing. In additon I can't recall the reason for the holes but it had to be either
1. overdriving (which I don't think I did, 100 watt Icom)
2. high swr which I know has been over 10 to 1, but I can't see how that could do it..
3. Light loading

But in any event for something to melt we need dissipation and only resistance can do that!

You might mention this is an older edition. Also, while I'd be the first to admit that Joe Carr probably knows a lot more about RF Design than I do, it's much more of a "cookbook" than a book with any significant theoretical basis (such as Hayward's, Orr's or DeMaw's books have); the title is -- IMO -- a little misleading.

I think you're making an inapplicable comparison.

The low-pass filters you're referring to have a relatively low loss when used as directed, it's true... but the "use as directed" condition usually mandates having the proper source and sink impedances on either side. The loaded Q is usually modest.

A transmatch being used to match a difficult load can be in a distinctly different situation. If the load is a harsh one (low R, high magnitude of X), tuning up can create a situation with a high network Q and high circulating currents in the tuner components.

The April '95 QST has an article which shows some actual calculations (and if I recall correctly the Handbook has a bunch of tuner loss tables).

One example in the QST article shows the results of using a T tuner to tune an antenna which is just too darned short. The tuner sees a load of 4.40 - j35 ohms. Although a match can be established with the specified tuner components, the estimated power loss in the tuner is almost 2/3 of the input (4.54 dB!). The transmission line eats enough 11.6 dB, in their example.

Granted, this is a rather pathological situation, but it does occur from time to time in the real world. I've heard numerous reports of people "burning up" their tuners by trying to match a low-resistance, highly-reactive load, and frying the coil. Some of the MFJ tuners seem to have a reputation for suffering from heat damage to the coils (the plastic coil form melts).

wrote:

>A whole new software industry has grown up because we
>don't require reliability in the software we use.

Hi Bob,

That brings to mind a case that should be drawing to conclusion today,
or at least sometime this week here in Washington state.

It bears on the last election where the Republicans were content to
win with the will of the people when the ballot count showed they were
200 votes, or so, ahead. Out of 2 Million, that was a thin margin of
1% of 1%.

This close count provoked a law mandated, recount which swung the win
to the other column. We have a law that changes the method of
counting to hand, if a certain margin exists, and the losing side is
willing to pay the burden. The Republicans were no longer content
with the will of the people, they expressed they would be more content
with the will of a judge. Hence, the fellow I was working with
(literally) collecting ballots pressed a suit against the election as
being fraudulent. Time will tell if the Republicans will go fishing
for some other entity before whom they will pray for succor.

I won't go into how much they would have lost by if the ballots they
wanted cast out came to pass - they want to win in court, not by
ballot count.

Anyway, this response is directed towards software reliability and
voting machines. We had testimony (from the Industry at a panel
presentation at the League of Women Voters) that software was not 100%
reliable, and we could never hope for it to be 100% reliable. Another
Industry representative, this time credentialed and not selling a
voting system, offered that Bank software counts paper everyday to
exceedingly high precision and accuracy. Much better than current
voting systems.

The salesman hemmed and hawed, threw a hissy fit, and fumed back that
hand counting was not nearly as good as machine counting. By and
large this is true (never mind his software didn't hit the mark of
being even close). Hand counting error rates average about 3 - 5%.
Machine counting error rates average about 2 - 3%.

The election results and the first recount showed less than 1% error
and in fact both this and the last hand (second re-) count agreed

within 1% of 1%. 1% of 1% was not good enough, but no one is suggesting we do this by hand next time when 2 - 3 % machines do it better. Yeah, a contradiction on the face of it, but they only have to convince 1 judge 51% instead of 48% (allowing for the boon of machine error) of 2 Million people.

As some Republican wag on the floor of the House offered across the aisle last November:
"No matter how hard you whip a dead horse, you are not going to win the race."
It's remarkable to see them flogging the road through the flesh stripped ribs of a carcass. I hope they can push it across the finish line so I can see what they call a victory lap.

Allodoxaphobia,
you must be talking about a tv 'splitter', rather than the balun
(remember, the balun has a 300-ohm cable on one end and a place to screw
coax on the other side.)
it wouldn't (normally) have 3db loss like a splitter would.

Surely I'm not the only one who wonders what counting method was used to arrive at those numbers. It's tempting to imagine that the hand counting results were checked by machine counting and vice-versa, then the results thrown into some wonderful statistical equation to arrive at those authoritative sounding numbers. . . or is there a hyperaccurate Third Method that The Conspiracy is keeping secret from us?

>But in any event for something to melt we need dissipation and only
>resistance can do that!

Hi Hank,

Unfortunately as much as you and I agree on that bedrock principle, others with Simpson Ohmmeter in hand would glare goggle eyed at us and say that plate has no resistance to speak of and that no amount of current through its Ohmic resistance could ever bring about enough heat to produce the effects so obviously witnessed. One of the most enraging questions I've asked
"If it is not the value I've offered, what value is it?"

Well, I've never been given a quantitative answer, however I've seen enough carefully crafted mathematical proofs in this group to replace substantive results so easily seen. There is some irrefutable logic in circulation that clearly reveals that what we've experienced just couldn't be.

Glasses will be need to be readjusted for such extreme myopic aberrations. There are two principles involved in what is called Plate Resistance, and the first and foremost is not even related to the plate at all. It is called the work function of the cathode emissivity. So, in fact it is more proper to refer to this usual loss as Cathode Resistance, not Plate Resistance. The cathode is the fundamental limit on power generated.

What Plate Resistance is, is the ill termed substitution for Plate dissipation. If folks want to work their Simpson, they would blow an aneurysm trying to measure the resistance from cathode (filaments have the same work function issue too) to plate. In fact, the hobby horse argument of it is not resistance at all, but some figurative charting artifice called a "load line" usually appears in the last gasp.

Plate Dissipation is resistance clear and simple in spite of the failure of conventional tools to measure a common physical property. Newton would have recognized it, it is called inertia.

Once the work function is overcome (the job of the grid), then Plate voltage dominates through the acceleration of charge beyond the grid, toward the plate. That stream of electrons (and there is no doubt about actual current flow in easily counted, significant populations of electrons) is elevated to 90% the speed of light. This current flow is entirely different from what current flows in the remainder of

the Plate load. That is also known as displacement current and electrons are shuffling along at a placid meter per second rate. Plate current and displacement current are equal in amplitude and phase, but not in motion nor kinetics.

NOW. When that same stream encounters the Plate - WHAM! If anyone here has walked into the wall, and NOT encountered resistance, then we will call you Casper.

Inertia reveals that to slow a mass in a distance results in acceleration (negative in this instance) and that property is called Force. Force over time expends calories and is expressed in any number of systems and units - Watts is one, Degrees is another. We could abstract to Horsepower and Candelas (the plate glows too).

We know the speed, not many here would give it much though, but none would know the length interval of going at that speed to going zero (0). It is roughly two atoms distance into the metal of the plate. I will leave those calculations of Force to the student to compute or I can provide it from notes of correspondence with Walt Maxwell and Richard Harrison from a round robin discussion several years ago.

Hank, does this fulfill your earlier question as to "what" is happening? I first gave you many examples, I hope this segue into real physics fills in their actuality. Too many correspondents demand that I open the source and point at a 50 Ohm carbon composition resistor that is the "source resistance."

Authorities have agreed on the results, yes. Most wonderful,
statistical equations are as simple as SUM/NUMBER. Few, I imagine,
rarely pen "wonderful" to their work or methods. Myself, I would shy
from offering what you should accept as authoritative - especially
when the leading defendant in this case has praised my contributions
(as inconsequential as I might think that effort was in proportion).

>or is there a hyperaccurate
>Third Method that The Conspiracy is keeping secret from us?

Hi Roy,

Sorry, when the population daily suffers so much admitted fraud, I
hesitate to offer conspiracy theories that could scavenge up the
crumbs of neglected booty. Perhaps you may be thinking of the
Association for Computing Machinery (ACM). They only host about 8000
pages relative to voting machines. Among them you might find some
amplification of methods, personalities, and challenges to the numbers
I offer.

Dialogue and corrections are always accepted.

> than that. What is the DC power input to the source electronics?

Who said anything about a Thevenin equivalent? The circuit I proposed isn't intended to be an equivalent of anything. It's a very simple circuit made with components whose characteristics are well defined and well known. The source is an AC steady state source (which I naively assumed was obvious). There is no DC power input to it. There are no "source electronics" -- there are no electronics at all. All elements in my example are simple electrical circuit components, as described in any elementary electrical circuits textbook.

There are 18 watts of "reverse power" in the transmission line, as calculated by those who embrace this concept. The source resistor matches the Z0 of the line. The source resistor dissipates 8 watts. Nothing "forbids" calculation of the dissipation of the resistor -- it's V^2/R, I^2*R, or V*I, take your choice. Any EE freshman, and I'd like to think most amateurs, including you, should be able to calculate it. The total power from the source equals the sum of the dissipation in the two resistors. The power dissipated by the load is the difference between the "forward power" and "reverse power", as you can easily see with a small amount of simple arithmetic. There is nothing "forbidden" about this simple circuit, except perhaps explanation by means of your theory.

Where's the "reverse power" going?

Any theory that doesn't work in a circuit composed of simple elemental electrical circuit elements is suspect to say the least. Are you saying yours doesn't?

Error rates in a voting system can be ascertained to any required
degree of accuracy just by repeating the counting process a number of
times.

It is reasonably assumed errors occur at random.

A comparison with a Hyperaccurate Third Method counting machine is not
required. It could not be trusted anyway.

No, sorry, I can't, and I don't believe there is such a thing. It's possible of course to find the input impedance of any wire antenna like the G5RV at each of the frequencies of interest. But transmission line lengths and impedances vary, which transforms the impedance seen by the tuner. Those impedance changes can be dramatic, and can result in widely varying tuner efficiency. On top of that, you have the variations in tuner topology and construction which makes a "typical" tuner also an elusive beast. I'd be very suspicious of any "typical" tuner loss figure, and wouldn't expect to see it in practice unless the conditions are spelled out really well and my setup was very similar.

You see, I'm not a true Guru. A real one wouldn't waffle like this, but would give you a positive answer, and you'd very probably never have reason to doubt it.

Cecil,

Nice try.

You first.

Describe how you set up this coherent wave/anti-wave pair that happily travel together for some indeterminate distance. Then I will describe what happens when at some arbitrary point and time they decide to annihilate.

I will repeat one more time, since you did not seem to understand previously.

* Maxwell's equations are all that is needed.

* Interference is *derived* from the correct application of Maxwell's equations. It is not an independent physical entity.

* Interference may be "intuitive" and it may help your understanding, but it adds precisely nothing to the physics of the problem. Everything you believe is buried in the magic of interference is already built into Maxwell's equations.

I did some measurments on a MFJ tuner into a dummy load. While I am not sure if the losses would be more or less than to an acutal antenna, I would assume it should be the best case . The losses were around 5 to 10 watts starting with 100 watts input depending on the band. I think 80 meters was the worse from 80 to 10 meters. This is a small tumer rated around 200 or 300 watts and has a built in wattmeter. This may account for a small aditional loss. I did not use this meter but did use 2 Bird meters , one on the input and one on the output to keep the input power constant at 100 watts.

Can you give us a magnitude, for example for a g5rv on 3.8 MHz fed with 50 feet of 50 ohm coax. Is it .5 or 5 dB?

Or we can be more specific and say we want to match
a 50 Ohm source to R 5000 -J720 using an MFJ989C. What loss is to be expected?

Granted there are cases of attempting to load a short (with respect to frequency) antenna that has extremely low values of R can cause large losses. I would think that a general statement could be made about antennas that are 1/2 wavelength or longer at the operating frequency and the magnitude of losses one could expect from the typical tuner.

Is there no way to quantify the losses, no rule of thumb, should we all throw our tuners away because they may have unpredictable horrendous losses? What steps should be taken by the average amateur to obviate these losses.

I am at a loss to understand how bad the losses are that you and Cecil refer to. Can you lead me from the darkness Sir!.

QST has on several occasions tested antenna tuners. The most recent one I found was from last year. The worst case I saw was something like 40% loss when matching an impedance of 6.25 Ohms on, I think, 40 meters. It is worth noting that the 2KW tuners will have less loss than the 300W jobs. Also, the loss depends on the impedance it sees, rather than the SWR. So, for an 8:1 SWR, the loss at 6.25 Ohms will be a lot worse than at 400 Ohms. Among other things, the loss will then depend on the length of the feedline. The high power tuners had a loss of less than 10% over most of the range.

It works just fine. Pfor = P1 + P2 + constructive interference.
But that still looks like a Thevenin equivalent to me, you know,
the one we cannot trust for internal power calculations.

Sorry again, I can't help you much. There are a number of tuner topologies in use (L, pi, high and lowpass tee, LCC, "ultimate transmatch" to name a few), and the loss of one compared to another can be quite different depending on the load impedance, even if all use the same inductor(s).

The information you gave is enough to calculate the impedance seen by the tuner, though, assuming your G5RV is 102 feet long and not one of the countless variations. Assuming a height of 40 feet over average ground, the impedance at 3.8 MHz seen at the input end of 50 feet of 50 ohm coax should be about 2.5 + j23 ohms (SWR ~ 27:1) if the coax is RG-8, or about 4.1 + j22 ohms (SWR ~ 17:1) if the coax is RG-58. (The SWR at the load will be greater than 60:1. You should maybe be worrying more about feedline loss than tuner loss.) I didn't take into account the effect of feedline radiation, which I'll assume is suppressed with a balun.

>
> Or we can be more specific and say we want to match
> a 50 Ohm source to R 5000 -J720 using an MFJ989C. What loss is to be
> expected?

Using the Z you specified or the Z I calculated, all that's necessary then is to obtain a schematic of the tuner and information about the physical construction of the inductor(s), calculate what settings will achieve a match, and find out which of these settings you're using. Then calculate the coil currents and from that the loss. I don't have a schematic of the tuner nor a physical tuner -- I haven't used one for 30 years or more except for a small homebrew tuner for correcting small mismatches to keep my QRP Field Day rig happy. So I don't have a clue. Perhaps someone else who has the tuner, the math ability, the patience, and the time will be willing to help you.

> Granted there are cases of attempting to load a short (with respect to
> frequency) antenna that has extremely low values of R can cause large
> losses. I would think that a general statement could be made about antennas
> that are 1/2 wavelength or longer at the operating frequency and the
> magnitude of losses one could expect from the typical tuner.

I think you can say that if the SWR is no greater than 2:1 or maybe 3:1, the loss in a properly designed tuner should be pretty low. Outside that range, like your 17 - 27 SWR example, I wouldn't speculate.

> Is there no way to quantify the losses, no rule of thumb, should we all
> throw our tuners away because they may have unpredictable horrendous losses?

Hm, are those the only two options? Why not use the tuner, make
contacts, and be happy? And if the tuner has a horrendous loss, why will
throwing it away help? You'll still be better off with it than without it.

> What steps should be taken by the average amateur to obviate these losses.

Adjust the feedline length for each band to present a moderate impedance
to the tuner. Cecil has posted quite a bit about this in the past. And
use a tuner with the largest coil(s) possible. You could set up jumpers
so you can change the topology of the tuner to pi, L, tee, etc. On each
band, try each configuration and, among those which effect a match,
choose the one that gives you the greatest field strength from your
antenna or the highest current to it.

Of course, you could do what I do -- I settle for other than all-band
operation, and make my antennas resonant or nearly resonant. When
matching is required, I do it at the feedpoint with components I've
characterized -- I know the antenna Z and the inductor Qs, so I can
calculate the loss. But most people don't want to do this, and happily
put up with whatever losses they get in exchange. Or you can get
something like the B&W terminated folded dipole, and put the losses at
the antenna instead of the tuner.

> I am at a loss to understand how bad the losses are that you and Cecil refer
> to. Can you lead me from the darkness Sir!.

Nope, sorry, I can't. What's the approximate value of resistors? I can't
answer that one, either.

For efficiency of the L-network tuner on different bands, and losses
in transmission lines and other data, download program DIPOLE3 from
website below.

The program covers dipole + balanced line + balun + coax line + tuner
L and C settings.

With one hit of a key the antenna system can be modelled as a G5RV.

Download program DIPOLE3 in a few seconds. It is also easy to find the
resonant frequencies of the G5RV.

> annihilate.

Sure, here's the two coherent reflected waves that cancel at a
Z0-matched impedance discontinuity in a transmission line.

b1 = s11*a1 + s12*a2 = 0

I'm sure you recognize the S-parameter equation for the reflected
voltage flowing toward the source which is the phasor sum of two
other reflected voltages.

They don't travel together for some indeterminate distance. They
are cancelled within the first dl and dt. And they don't annihilate.
They simply cancel in the rearward direction.

Incidentally, if you square both sides of the equation you get

b1^2 = s11^2*a1^2 + s12^2*a2^2 + 2*s11*a1*s12*a2

Pref1 = rho^2*Pfor1 + (1-rho^2)*Pref2 + interference

The forward voltage equation toward the load is b2 = s21*a1 + s22*a2

523. Very small FM xmtr antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-07 03:51:31 UTC
From: terryc@sweetwaterhsa.com
Message-ID: <1118116291.864145.297870@g44g2000cwa.googlegroups.com>
Source record: 75539

Hello,

I have a portable music player (MP3, etc) with a built-in FM transmitter. The original transmission antenna is a thin foil thing shaped like a very elongated letter 'E'. It has terrible range; aftermarket transmitters will nearly always do better.

Could somebody point me in the right direction for making a suitable replacement that will still fit inside the very tight (2"x3"x almost nothing) available space? Is it possible, for example, to make a simple (1/48th wave?) dipole antenna of some sort that will be an effective transmitter?

Many thanks for your help to one entirely ignorant in this field.

Is there no way to quantify the losses, no rule of thumb, should we
all
throw our tuners away because they may have unpredictable horrendous
losses?

In general I do....I don't use a tuner for any of my everyday
antennas...

What steps should be taken by the average amateur to obviate these
losses.

Quite simple really. Use the very minimum inductance needed to get
a usable match. I once did tests to determine the appx amount of
tuner loss when tuning properly vs improperly. When using an excess
of inductance to match, I saw tuner losses approach 20%. IE: 20w out
of 100w. When carefully tuning, using the very least inductance, this
loss could be reduced to a value nearly unreadable. BUT!!! This was
on a resonant 50 ohm system. You could expect the losses of an extreme
mismatch to be higher, even if you tuned very carefully. The losses
and
coil warming when feeding a 1/2 size dipole with a T net tuner are well
known.
Thats how I got a free MFJ 989c when a friend of mine couldn't keep
from
frying the plastic coil forms. He bought a nye viking, and gave me the
989c.
Which I've used since with no problems at all....It wasn't really the
tuners
fault...He was abusing it trying to feed a 1/2 size dipole, and then
running a
TL-922 flat out on top of that...:(MK

Your use of "Dr. Best's conventions" only muddles the matter -- neither I nor probably any of the other readers have any idea what this is. In any event, the numbers you produced are volts. I and many others know how to calculate forward and reflected voltages and currents, and their sums. What's at issue here is where the imaginary waves of average power are going, what they're bouncing off, and why. Correct me if I'm wrong, but power is generally expressed in watts, BTUs per hour, or other more arcane units, but not volts.

Let's try again. The source is providing 40 watts, 32 watts of which is delivered to the transmission line. The transmission line is transferring this 32 watts of power to the load. In the transmission line, we can calculate that there's 50 watts of "forward power", and 18 watts of "reverse power". How much of that 18 watts of reverse power is going through the source resistor to reach the source to "engage in destructive interference"? What does it interfere with? How does whatever it interferes with get there? Does any of the power going either way, forward or reverse, get dissipated in the source resistor? If so, how much and why? If not, why not?

In your "explanation", I don't see a single figure in watts, except that "we have 23 watts of constructive interference occuring toward the load". (Where is this interference occurring, that is, just where is the point "toward the load" located? Where did the 23 watt figure come from? How much of it is "forward power" and how much "reverse power"?) It's not an explanation at all, but hand-waving.

And why do you insist that every combination of voltage source and resistor be a "Thevenin equivalent"? I suggest you go back and read your basic circuits texts, where you'll find that a Thevenin equivalent is a circuit which is used to substitute for a more complex linear circuit to simplify analysis. The electrical circuit components used here are not a substitute for anything. And there's no rule, except something apparently stuck firmly in your mind(*), which prohibits calculating the power dissipated in a resistor. No matter what it's connected to. I make no claim that the power dissipated by the resistor represents anything but the power dissipated in a resistor, that the resistor represents anything but a resistor and the voltage source anything but a voltage source. It is not a Thevenin equivalent, it's a painfully simple electrical circuit (alas, so simple it's difficult to obfuscate). It doesn't matter if you can trust a Thevenin equivalent for internal power calculations. There is no "internal power" here -- it's all out in the open where we can easily measure and calculate it.

There's nothing in that "black box source" except an ideal voltage source. You can find a description of this fundamental electrical circuit component, including its complete terminal characteristics, in the circuit analysis textbook of your choice. People skilled in the art are able to calculate the power it produces by multiplying v across it times i flowing from it, and the average power by applying the mathematical definition of average to the calculated power. In this case, it produces an average of 40 watts (100 volts times 0.4 amp).

So please tell us how many watts are going where, what they do when they get there, and why. If you can't, you don't have a theory at all.

(*)Forgive me, I just can't shake the image of a certain memorable scene from the movie "The Long Kiss Goodbye" as I write this.

Why bother, unless you're having a problem with the heat? 20% loss is
just about exactly 1 dB.

Source record: 75546

Dave C wrote:
"What point is considered the focuspoint of the horn?"

The equation for the parabolic reflector`s surface contour is:
R=2L/1+cos theta
R=distance to a parabooid`s surface point from focal point
L=vertex to focal point distance
theta=angle made by a direct ray to a surface point with the axis of the parabola

A feeedhorn radiates into the reflector`s focal point, usually on the parabola`s axis. All rays perpendicular to the plane across the mouth of the paraboloid converge at the focal point due to reflection.

At the plane across the mouth of the paraboloid, the total distance from the mouth to the reflector and from the reflector to the focal point is the same for every point on the plane. Rays come and go in parallel routes to its axis, in and out of the parabola, and all of these pass through its focal point.

A parabolic reflector tends to collimate radiation from its focal point into a beam parallel with its azis. Reciprocity rules so that incoming radiation has the same directional characteristic.

Best regards, Richard Harrison, KB5WZI

My 2 cents on the subject of tuner loss.
A tuner will Always introduce more loss to the system.
If the total power output of the transmitter is not improved(ie, at < 2:1 SWR), then using the tuner to reduce SWR to 1:1 is counter productive, isn't it?
In other words, getting the SWR down to 1:1 from anything <= 2:1, will always cause a reduction in total power out.

For me, not so. The manual for my Icom 735 says it is designed to
handle 1:1.5 swr, but to try to get it as close to 1:1 as possible.

I just tried an experiment on 20 meters with my 80 meter dipole and an
MFJ 989c tuner. At 1:1 swr, the meter measures 110 watts out; raising
the swr to 2:1 lowers the metered output to 20 watts. So I'm not sure
what the advantage of running a higher swr is.

> transferring this 32 watts of power to the load. In the transmission
> line, we can calculate that there's 50 watts of "forward power", and 18
> watts of "reverse power".

And it is easy to prove that the source has generated 50+18=68
watts that have not been delivered to the load. So I ask
you: Where are those 68 joules/sec located during steady-state
if not in the forward and reflected power waves? Why will
68 joules/sec be dissipated in the system *after* the source
power is turned off?

If those 68 joules/sec that have been generated by the source
but not delivered to the load are not in the forward and reflected
power waves, exactly where are they located? There's really no
sense in continuing this discussion until you answer that question.
Everything else is just a side argument.

The answer to that question will expose the errors in your premises.
You are apparently assuming there is not enough energy in the system
during steady-state to support the forward and reflected power waves.
But that exact amount of energy was supplied during the power-on
transient state and will be dissipated during the power-off transient
state. If it's not in the forward and reflected power waves, you
are going to have to store it somewhere else. Where is that
somewhere else?

The source has supplied 68 joules/sec that has not reached the
load. The forward and reflected power waves require 68 joules/sec.
That you don't see the logical connection between those two equal
energy values is amazing.

But I will get you started on an understanding of the component
powers using an S-parameter analysis.

> How much of that 18 watts of reverse power is
> going through the source resistor to reach the source to "engage in
> destructive interference"?

reference the S-parameter equation: b1 = s11*a1 + s12*a2

I calculate 11.52 watts. (s12*a2)^2 = 11.52 watts

The other 6.48 watts are in (s22*a2)^2 where |a2|^2 = 18 watts

> What does it interfere with?

From the S-parameter equation above, it obviously interferes
with s11*a1 .

Please reference HP App Note 95-1, available on the web. It should
answer most of your questions, in particular pages 16 & 17.
|a1|^2 = Power incident on the input of the network
|a2|^2 = Power incident on the output of the network
|b1|^2 = Power reflected from the input port of the network
|b2|^2 = Power reflected from the output port of the network

Cecil,

You completely ducked the question. How did those waves get there in the first place? Hint: there are no laws for conservation of waves or continuity of waves.

It is easy to set up a problem with physically unrealizable inputs. It is pointless to try to solve such a problem, however.

We've been around this track a couple of times before. Neither of us has changed.

Bye.

Reg,

That's assuming that those doing (or controlling) the counting are honest.
But unfortunately, honesty doesn't seem to be valued very highly either.
There was an inner city Philadelphia precinct that had a 100% voter turnout
during a recent presidential election...

Richard
Thanks for your explanation, I'm still thinking it over since its been 40 years since I've studied any tube theory. .. I recall many years ago watching a guy trying to fix an old radio. IIRC it had an 80 rectifier and right after the radio was turned on and started to warm up a blue cloud could be seen in the tube as the plates started to turn redder and redder. He would turn it off, change a part and check it again. I don't think he fixed it before the 80 went south. Later I figured out that he probably had a shorted filter cap.
In this case the diode's plate dissipation rating was exceeded and it melted. The electrons slamming into the plate have a lot of kinetic energy to transfer. and heat up the plate. This results in lower efficiency as this power isn't delivered to the load. Now the diodes resistance can be easily calculated but I'm not sure how to visualize it. Is this where your term cathode resistance enters the picture?
tnx

Gene Fuller wrote:
> You completely ducked the question. How did those waves get there in the
> first place? Hint: there are no laws for conservation of waves or
> continuity of waves.

I answered the question in another posting. The waves got there
during the power-on transient state. Conservation of energy is
assumed. Hope you don't disagree with that principle.

If we make Roy's lossless 50 ohm feedline one second long (an
integer number of wavelengths), during steady-state, the source
will have supplied 68 joules of energy that has not reached the
load. That will continue throughout steady state. The 68 joules
of energy will be dissipated by the system during the power-off
transient state.

What you guys are trying to do is hide 68 joules of energy that
cannot be destroyed. Where can you hide it in a transmission line
to prove that it is not there in the forward and reflected waves?
What is your agenda in trying to deny/hide/disguise/ignore that
68 joules of energy?

In the one second example, the forward and reflected waves require
68 joules of energy for their existence in the feedline. The source
has supplied 68 joules of energy that has not yet reached the load
so it must necessarily still be in the feedline. Wonder where
the energy in the forward and reflected waves came from? Shirley,
you jest!

Incidentally, QEX wants to publish my article.

During the Lyndon B. Johnson senatorial election, some voters
in Jim Wells County arose from their cemetery graves and
voted for Johnson. Others registered to vote in alphabetical
order. When Gov. Price Daniels showed up with the Texas
Rangers, the court house had mysteriously burned down along
with all the voting records and the rest is history.

If you can't get the internal SWR meter on an Icom 735 (or similar rigs) down to exactly 1:1 then either there's something wrong with the tuner or with the tuner operator.

The tuner either works or it doesn't. There's no half-way house. Without a tuner anything can happen. And it usually does.

There are far too many sleepless nights unnecessarily caused by the SWR meter not being in the right imagined ballpark. Just ask yourselves is the transmitter loaded with roughly 50 ohms or isn't it. The SWR on the feedline hardly matters two hoots - the so called SWR meter doesn't measure it anyway.

Do G5RV addicts realise that under even the best conditions the SWR on the feedline is as high as 10-to-1 regardless of what the meter says. But it doesn't seem to worry them.

Reg.

There's only one in every half a million of radio amateurs who have a copy of this document, or have ever heard of its existence, let alone having any chance of finding a readable copy of it within the next dozen years. By which time they will have changed their hobby to keeping tropical fish or making Newtonian telescopes. Or just died.

In all likelihood they won't be able to make any sense out of it anyway.

Cec, why do you bother to mention it? (smiley)

Reg.

What you say is true for roller inductor tuners, Reg,
but most tuners have switched inductors. The perfect
inductance may not be possible.

I realize that a tuner is not 100% efficient, but when I hook up my 80
meter dipole and listen on 20 meters (the wire is fed with coax), the
signals are stronger when tuned thru the tuner rather than direct from
the antenna. Not to mention that when I transmit, the radio is
operating on reduced power with the dipole direct. I realize that
there is considerable loss in my coax (I am using garbage and know it)
and that I am taking a loss thru the tuner, but it is a better option
than direct thru the coax alone.

560. faraday cage apartment / cell phone

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-07 17:30:13 UTC
From: netkev@gmail.com
Message-ID: <1118165413.190574.198090@g43g2000cwa.googlegroups.com>
Source record: 75572

I searched the archives and found this question addressed but not fully. I have a verizon cell with a dual-band radio 800/1900. I get service everywhere except...my new apartment. Ofcourse, probably a typical scenario. The second I walk into the apt, the signal drops to nothing. Outside, I have full strength. My assumption is that it must be the construction of the building that's creating some type of faraday cage.

The obvious solutions to my problem are:
Buy a new phone from a different provider
Use a land line
Purchase a cell repeater for the 800/1900 freq (unsure which is being used in my area but I will find out)
Connect an external antenna to the phone

Switching providers is not an option due to the fact that I've tried 'em and Verizon has the best coverage in my area...w/ the exception of my apt.

I hate the idea of having multiple phone numbers so I dont want a land line.

I am honestly considering the cell repeater but the cost is putting me off. They cost around $500-700. I get the feeling this could be built for pretty cheap but I'm not an electrical engineer so ... Apparently, they use them in my office building for sprint since our company has a very large contract with them.

I'd prefer to remain wireless so an external antenna, unless it's small enough to strap to my flip phone(which I have been unable to find) is out of the question.

What about a passive antenna? I know that traditionally they are looked down upon and can even cause signal degradation but in my case, the signal is VERY strong just outside. Is it a possibility? If so, what size antennas should I purchase for the 800 or 1900 bands? Obviously, I will have to figure out which is being used in my area but there must be a simple formula for the size. Also, coaxial type, placement, etc?

I'm using the samsung sch-i600 smartphone with windows mobile 2002 on the verizon cdma network. This phone is dual-band, digital. No amps/analog.

Any other ideas?

My TS870 has an menu option for setting the "good enough" SWR using
the built-in tuner. The limits can be <1.2:1 or <1.6:1.

1:1 is not an option nor is it desired. If the feedback loop was
tight enought to always try to achieve 1:1 it would probably never
stop hunting.

>

Nor is it required. With three reactances, coarse setting one and
varying the other two can achieve a perfect match. As I have said
many times, this may not be optimum from a loss or BW standpoint, but
you can get a match.

[No, I didn't. Cecil wrote the following paragraph.]
>
> We are not going to get anywhere until you admit there is 68
> joules/sec in the feedline that haven't yet made it to the load. Once
> you admit that fact, everything else will be moot.
>
I never said a word about how much energy is stored in the feedline; it's irrelevant. It's stored there during the initial charging to the steady state condition, and the same amount remains there until the steady state condition no longer exists. It's exactly like the DC charge on a capacitor or a DC current through an inductor (which, in fact, is exactly what the feedline stored energy consists of) -- it doesn't have any effect on an AC analysis.

[I did write this one.]

>> Let's try again. The source is providing 40 watts, 32 watts of
>> which is delivered to the transmission line. The transmission line
>> is transferring this 32 watts of power to the load. In the
>> transmission line, we can calculate that there's 50 watts of
>> "forward power", and 18 watts of "reverse power".
>
>
> And it is easy to prove that the source has generated 50+18=68 watts
> that have not been delivered to the load.

Surely even you can do the basic circuit analysis which shows that the source is continuously generating 40 watts, not 60. 32 of those are delivered to the load and 8 to the source resistor. I guess you mean 68 joules -- but as I said, it's irrelevant.

So I ask you: Where are
> those 68 joules/sec located during steady-state if not in the forward
> and reflected power waves? Why will 68 joules/sec be dissipated in
> the system *after* the source power is turned off?

The line's stored energy will be dissipated in either the source or load resistor or both when the source power is turned off. But we're doing a steady state analysis here.

>
> If those 68 joules/sec that have been generated by the source but not
> delivered to the load are not in the forward and reflected power

> waves, exactly where are they located? There's really no sense in
> continuing this discussion until you answer that question. Everything
> else is just a side argument.

You tell me -- they can be anywhere you'd like. Just answer the simple
questions about the power "waves".

>
> The answer to that question will expose the errors in your premises.

What exactly is my premise, please? All I've done is to give the
currents and powers at significant points in the circuit. Are any of the
values incorrect? It's you who has the premise, not me.

> You are apparently assuming there is not enough energy in the system
> during steady-state to support the forward and reflected power waves.

I'm making no such assumption. I'm questioning the existence of
traveling waves of average power, and so far you've failed to give any
evidence to convince me otherwise.

> But that exact amount of energy was supplied during the power-on
> transient state and will be dissipated during the power-off transient
> state. If it's not in the forward and reflected power waves, you are
> going to have to store it somewhere else. Where is that somewhere
> else?

You tell me. My analysis doesn't need to consider the stored energy at
all. Apparently yours does, so have at it.

> The source has supplied 68 joules/sec that has not reached the load.

I think you mean 68 joules.

> The forward and reflected power waves require 68 joules/sec.

The "forward power" is 50 watts. The "reverse power" is 18 watts. It
requires 32 watts to sustain this. That's the amount of power flowing
through the transmission line, from source to load. That's 32
joules/second, not 68. If the line were open circuited, the forward and
reverse powers would be equal, and it would take no power to sustain them.

That you
> don't see the logical connection between those two equal energy
> values is amazing.
>
> But I will get you started on an understanding of the component
> powers using an S-parameter analysis.
>

Where will you find to put those all-important 68 joules in an
s-parameter analysis? That's a steady state analysis.

>> How much of that 18 watts of reverse power is going through the
>> source resistor to reach the source to "engage in destructive

>> interference"?
>
>
> reference the S-parameter equation: b1 = s11*a1 + s12*a2
>
> I calculate 11.52 watts. (s12*a2)^2 = 11.52 watts
>

Finally, an actual answer. So of the 18 watts of "reverse power", 11.52 watts is making it to the source to "engage in constructive interference". Does any of it get dissipated in the source resistor, or does it just slide through unscathed?

> The other 6.48 watts are in (s22*a2)^2 where |a2|^2 = 18 watts

What's (s22*a2)^2? The forward power wave? The reverse power wave? If it's something else, does it have a name? Where does it go? Is it getting dissipated in the source resistor, reflected at the transmission line/resistor interface, reflected at the source/resistor interface, get radiated, or what?
>
>> What does it interfere with?
>
>
> From the S-parameter equation above, it obviously interferes with
> s11*a1 .

What's s11*a1? It must be something inside the source. The source is just that, a source. It has (AC) voltage and current, 100 volts of voltage and 0.4 amps of current. Does s11*a1 reside inside every source, or only some special ones? Apparently 11.52 watts of this s11*a1 gets cancelled by the reverse power wave. How much of it is left over?

>
> Please reference HP App Note 95-1, available on the web. It should
> answer most of your questions, in particular pages 16 & 17. |a1|^2 =
> Power incident on the input of the network |a2|^2 = Power incident on
> the output of the network |b1|^2 = Power reflected from the input
> port of the network |b2|^2 = Power reflected from the output port of
> the network

Nope.

Enough hand waving and evasion, we've been here before. [Of all the questions, the sole quantitative answer was "(s12*a2)^2 = 11.52 watts".] I'll leave you to the folks who regard this kind of gobbledegook as convincing evidence. Have fun -- I've got actual work to do while you take care of the visionary leadership part.

<kolesnik@sbcglobal.net> wrote:

>Now the diodes resistance can be
>easily calculated but I'm not sure how to visualize it. Is this where your
>term cathode resistance enters the picture?

Hi Hank,

Getting electrons to "boil" off the cathode (or filament, same thing)
is not a simple task otherwise there would be no filaments needed.
Even with filaments, Edison current is not very considerable unless
you add a monomolecular layer of metal to the surface of either the
filament, or the cathode.

You may note that some tubes are described as having "Thoriated"
filaments. This is that monomolecular addition. Its purpose is to
lower the W, the work function of the interface.

It is far from odd how physics demonstrates at every stage and in
every discipline that interfaces where there is mismatch, there is
difficulty in transfering power. When an electron from the interior
of the metal crystal approaches the surface, it is repelled by that
interface due to the potential of the work function, and is attracted
by the bulk material behind it. The Thoriated surface offers a
matching mechanism between the bulk metal and the free space beyond
the surface. In classic Optics this is known as Index Matching.

To give examples as to how well a monomolecular addition performs:

A Tungsten filament (no treatment) offers a current density of ï¿½A/cMï¿½
This makes for a baseline.

A Thoriated Tungsten filament offers a current density of 4A/cMï¿½

Then we step back to a cylindrical cathode employing Barium.
Such a cathode offers a current density of ï¿½A/cMï¿½

That seems rather regressive to use a cathode, but temperatures are
telling. The simple Tungsten filament is operating at 2500ï¿½ K and the
cathode needs only to simmer along at 1000ï¿½ K. This gives
considerably longer life and more efficiency (most of the power for
heating is lost through radiation). Needless to say, cathodes find
more application in low power circuits, or their surfaces are treated
with other low work function metals for greater emission.

Now, when you add a potential gradient, you also lower the work
function of the surface (but it is always an advantage to have it

lowered going into this game). This is called the Schottky effect. One might be tempted to simply ask, why don't we up the voltage and discard the filament? This device would be called a Cold Cathode but the potential gradient then rises to the level where you run the risk of secondary emission.

When that electron stream strikes the plate and raises the temperature, it is just short enough power to present this secondary emission. But if we were to run at 17KV or so, then the electron stream would be so aggressive as to produce high energy effects such as X-Ray emission.

So, to return to the resistance of this all, we have physical impositions of cathode surface area (probably offering the prospect of being greater than filament surface area), current density, and potential difference. Discarding all the extraneous surface units (cMï¿½) and employing the proper division (E/I) we have a resistor that glows in the dark under extremes of operation. How this fails to be source resistance is strictly handwaving and the schematic symbolic mysticism of demanding a carbon composition resistor.

I will be sending you some photos of my final installation. I did a number of tests comparing how tight you can wind the loops. I was amazed at how non critical it was, considering all the dire warnings one receives from the old wife's tales.

Aside from all the ham bands, I have the need to get down to 3.347 MHz as well. My setup with the thumbwheel digital rotary switches lets me look at my chart, see 3.5 MHz needs 39 additional feet and set 39 in the switches, I built a box outside the house with 4 dowel rods to wind the loops around. It worked out great both mechanically and electrically.

After I inserted the relay box, I cut additional feedline off the 90 foot feedline so the output side at the end of the coax agreed with the original readings. Once that was accomplished all the plots were in agreement with the predicted except on 40 meters. Predicted should have been 7.3, actual was 6.8 MHz. Easy enough to correct for, but have not yet figured out what causes it. All other freqs were spot on.

Worst SWR is 1.8:1 I am a happy camper. On 75 an A/B test shows no difference was noted between it and a 75 meter dipole.

I need to A/B it on the other bands yet.

My method of 1,2,4,8 and 10,20,and 40 feet uses extra feed line, but is made up for in the ability to enter feet directly on the switches.

Three other folks here are constructing a duplicate.

Of Course you are, all horror stories aside.

Don't confuse the angels dancing on the pinheads around here with practical world experiences. The best solution is to increase the length of your dipole to 130 feet and feed it with 100 foot of 450 Ohm ladderline. Connect a piece of coax with a ferrite bead choke to the 450 Ohm line. Your tuner will love you and you can use all bands from 80 on up.

The electrical plug on your rig has losses that are about as meaningful real world..

My 132 foot dipole is fed by lengths of 450 Ohm line of lengths depending on frequency. The first part acts as a matching section to achieve 50 Ohms. This feeds an electrical 1/2 wavelength 450 Ohm section the 50 ohm impeadence is seen by the rig, while maintaning a 9:1 swr on the 1/2 wave section. 450/50=9:1

Yes. The women never fail to make me accountable and responsible... so should women be held to the same standard... there is much here which is wrong... last I heard birth control is widely available, probably even to 12 year olds... a grown woman should be able to make use...

However, I have never lived in fear from having common citizens in possession of weapons... it is the desperate criminal who I fear with the weapon--and not having good citizens with guns to deal with him...

I don't doubt the criminal will always have a gun, I fear a gov't who denies it citizens... when a gov't becomes in fear of its' citizens something is wrong alright, and it NEVER is the majority of citizens!

Warmest regards,
John

Hi Fred,

We guarantee the right of EVERY adult in Iraq to carry a gun - no
qualification whatever. Works like a charm doesn't it?

Think how it would transform North Korea! I would hope that in their
exuberance, crossing the DMZ, they didn't step on one of the
million-plus landmines as they came to embrace their brethren in Seoul
30 or so miles south.

Try simple installation using leaky coax (radiating coax) cable.
Put some antenna at the end and set it in place where signal is ok.
Then use standard coax - next in Your apartment connect few meters of
leaky coax hidden on the floor for example.
This could help as it's common solution in buildings.
If You doesn't have any possibility to buy leaky coax /it costs
quite - about 4 Euro per meter/ then on the other side of coax from
antenna - connect another antenna - just like the first one.
Those solutions are quite cheap to test.
Good luck.

Regards
Andrzej Rusiecki

What causes it is the feedpoint impedance of a one wavelength
dipole is very high and therefore easily upset by the surroundings.
A low impedance feedpoint impedance is not easily upset by the
surroundings. It's the same concept as using a 20k ohms/volt
voltmeter to measure the cathode voltage or the screen voltage
of a tube. One will give correct results and one won't.

> it's irrelevant.

Do you think it is random coincidence that the amount of energy
stored in the feedline is *EXACTLY* the amount of energy required
by the forward and reflected waves???? The fact that you think
it is irrelevant is simply a flight into a wet dream fantasy.

> It's stored there during the initial charging to the
> steady state condition, and the same amount remains there until the
> steady state condition no longer exists. It's exactly like the DC charge
> on a capacitor ...

What a coincidence! It's *EXACTLY* the amount of energy required
by the forward and reflected waves that you say don't exist - and
it's RF photons, not DC, so it must travel at the speed of light!
You cannot store photons in a capacitor.

> Surely even you can do the basic circuit analysis which shows that the
> source is continuously generating 40 watts, ...

Of course, but during the power-on transient period, 68 watts is NOT
delivered to the load. Please don't make me waste my time calculating
the forward and reflected power during the power-on transient period.
When you actually do those calculations, you will agree with me that,
during the power-on transient phase, 68 watts of power has been stored
in the feedline and remains there until the power-off transient phase.
It is *EXACTLY* the amount of power required by the forward and
reflected waves.

> The line's stored energy will be dissipated in either the source or load
> resistor or both when the source power is turned off. But we're doing a
> steady state analysis here.

Which must necessarily include the energy stored in the feedline during
the power-on transient condition because it is *still there during
steady-state*. Ignoring the energy stored in the feedline during the
power-on transient phase is both irrational and illogical. It could
even be bad for your mental health.

> What exactly is my premise, please?

from my earlier posting:

>> You are apparently assuming there is not enough energy in the system
>> during steady-state to support the forward and reflected power waves.

> I'm making no such assumption.

I'm sorry, Roy, but that is just BS! Either you admit there is enough
energy to support the steady-state forward and reflected waves or you
don't.

> My analysis doesn't need to consider the stored energy at all.

And that is exactly why your analysis is wrong. You have, once again,
been seduced by the steady-state model and are spreading old wives'
tales as a result. Hopefully, you don't really want to do that.

>> The source has supplied 68 joules/sec that has not reached the load.
>
> I think you mean 68 joules.

68 joules/sec in your original example. 68 joules in my one-second-
long feedline example.

> Where will you find to put those all-important 68 joules in an
> s-parameter analysis? That's a steady state analysis.

The 68 joules were stored in the feedline during the power-on
transient phase. They are still there during steady-state. An
S-parameter analysis yields the correct results because it
includes the reflected power, |a2|^2, as an energy source,
something you deny. Wonder what the S-parameter analysis folk
know that you don't choose to admit?

> Finally, an actual answer. So of the 18 watts of "reverse power", 11.52
> watts is making it to the source to "engage in constructive
> interference". Does any of it get dissipated in the source resistor, or
> does it just slide through unscathed?

It never encounters the source resistor as it is re-reflected by
wave cancellation, not by an impedance discontinuity. I have a QEX
article coming soon that will explain the details. Stand by. With
an unprejudiced open mind, you might actually learn something.

> What's (s22*a2)^2?

Same as (1-rho^2)*Pref2 in ham terms. Reflected power from the
load that is re-reflected back toward the load by an impedance
discontinuity.

> What's s11*a1?

Same as Vfor1*rho in ham terms. Forward voltage that is reflected
back toward the source by an impedance discontinuity.

> I'll leave you to the folks who regard this kind of gobbledegook as
> convincing evidence.

Do you realize what intellectual shape you would be in if you had
adopted that attitude when you were one year old? :-)

Richard,

This has been an entertaining monologue on electron tubes. (Must be International Fractured Physics Week on RRAA.)

I won't attempt to address the numerous howlers, since Henry seemed satisfied with your tale, but you might want to rethink the item you "correct" in this message.

Secondary electron emission also occurs at much lower incident electron energies. As a metrologist you are most likely familiar with electron microscopy. Secondary electron emission is the typical mode of detector operation. The incident electron energy in modern SEM's is now in the range of 500 to 700 volts.

One of the reasons for adding more grids in vacuum tubes is to manage secondary emission from the plate. This occurs at much less than 17 kV.

73,
Gene

Yeah, my thoughts exactly. I think it won't hurt (my wallet or my phone) to try such a passive repeater. I will try and see if I can source leaky coax too. I'll let you guys/gals know how it goes.

Actually, I read a while back somewhere that a company had developed
wall paper to do specifically that. They could manufacture it for
specific freq. ranges.

Hi Gene,

Sure, but not X-Rays which attend Cold Cathode tubes (skipping the gas
filled tubes I've already touched upon) and do require elevated
potentials to be so useful (that they become dangerously useful).

Glad you won't attempt the other howlers.

Well then, see, the problem is that you think you must share your
opinions, observations, religions, points of view and repeat the fact
you consider me an a$$hole...

I simply want to have you to have a good time and see no harm in your
bad behavior and so indulge you... to which you petition me for redress
of your grievances which all seem to be centered about me "ceasing and
desisting", and since this is rather presuming on your part and demands
another (namely myself) indulge you--and since I have no other course
but to deny you--you continue to whine, hoping that will have an
effect... and it does, I ignore it... and so, we continue...

John

Because you see 50 ohm (more or less) at the input of your "450 ohm"
(more like 400 ohm) line with an arbitrary impedance at the other end,
you incorrectly conclude the 450 ohm, variable length line is
operating at 9:1.

It appears that you've copied Cecil's design (ingenious BTW) but even
he admits to anywhere from 6:1 to 13:1 on his line.

For discussion purposes let's say that a 132 foot dipole, 50' above
average ground operated on 3.5 MHz has a feedpoint Z of about 61 -j63.
That's about SWR = 7.5 using 450 ohm as a normalizing factor.

Except for the effects of loss, the SWR *everywhere* on the line is
7.5:1. You don't get to say that 1/2 wavelength of it is operating at
9:1 and some other part is operating at something else.

Change the frequency to 7 MHz and the SWR is ~10:1 and so forth.

I have a 400 foot loop that is more triangular than square but it
still seems to work pretty well. The biggest difference between our
antennas is how they are fed. I use 450 ohm ladder-line to a balanced
tuner (Johnson Matchbox) to my FT-897D. According the Yaesu's display
a suitable match can be obtained on all bands except 30 and 60 meters.

I can also use the antenna on six meters with a homebrew matchbox for
that band. A two meter matchbox is in the works.

The impedance, is that the right word?, of a loop can be several
hundred to several thousand ohms. As you have found, the antenna is
not a fifty ohm load.

>My installation is far from ideal. First, the antenna for about ï¿½ the

Ack, do not shrink the loop!!!!! The tuner you have can be used with a balanced feeder, the built-in balun should be satisfactory. Try feeding your loop with 450 ohm ladder-line from the tuner and things should improve significantly.

Source record: 75618

Nonsense Wes, take the case of an antenna that is of sufficient length, height, or what ever so that at the antenna is exactly R 50 J0.

I feed it with an electrical 1/2 wave length of exactly 450 Ohm feedline. The 50 Ohms from my antenna is repeated at the other end of the feedline. An SWR bridge calibrated for 50 Ohms and my rig see 1:1.

Would you deny that the SWR on the feedline is 9:1? What is my SWR?

Can I say I have 1:1 at the ends and 9:1 anywhere on the feedline? I do get to say it!

Now if you want to argue that it will never be exactly 9:1 because the feedline is never exactly 450 Ohms, or the antenna has a reactive portion, you will have to change the subject. No generalization is valid, including mine that I have a 9:1 by design. But I suspect you already new that and decided to increase the quantity of fly crap in the pepper.

The Journal of Irreproducible Results could also be persuaded to publish that claim, Cecil. Any implication that almost half of Maxwell's equations are superfluous should easily qualify as an irreproducible result. :-)

619. Correct Antenna Takeoff Angle?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-08 02:12:53 UTC
From: Al Lorona <al_lorona@agilent.com>
Message-ID: <1118196774.758472@cswreg.cos.agilent.com>
Source record: 75484

Hi, Everybody,

How does one determine the correct antenna takeoff angle to communicate over a certain distance?

I can't find any references anywhere that discuss this, taking into account all of the variables: height of ionosphere, frequency, etc.

Here's a practical example of when it would be important to know this. Say you are going to put up a dipole antenna for 20 meters specifically to communicate to a friend 2000 miles away during the day. The takeoff angle of the major lobe varies widely as the antenna is raised from ground level to 1 wavelength above ground, so presumably there is a 'best' height for the antenna to put the major lobe right where it needs to be to skip to your friend's QTH.

The trouble is, we do not seem to have a good way to determine this 'best' height ahead of time. One would, I guess, have to vary the height of the antenna while the other station monitored your signal strength, and one would have to do this over several days, weeks, or months to get good, averaged data. But... isn't there a better way to do this?

Regards,

Al W6LX

This is at least four questions
1. How many operations;
at least two to satisfy the statement responded to
2. identical input;
self validating, however this constraint is unnecessary
3. valid input;
what does it matter? the response is identical
4. every time
time is an illusion, a computer only knows now. This is why it ALWAYS
does the same thing. If it didn't, would you use the ATM machine?
Would you fly on a 757? Would you go on a green light?

If it didn't, would you use that voting machine again? What if they
said it was good enough and you had no choice and no paper trail?

.....

Well, the Judge smacked down the gavel yesterday and threw the
Republican's challenge out. Nothing was left to appeal on, "the law
is clear," said the Judge, "take your beef to the lawmakers...."

Unmentioned on national feed, was Rossi's whine: "Can't take this to
the Supreme court because of its political bias." Luckily his
progesterone laced complaint wasn't raised in this Republican
dominated county. After all, if you can't get a straight deal from
Olympia, what kind of shaft job did you get in your own hand-picked
court?

Too bad too. I wanted to see more action. This generation of fops
and hairless, overweight pill-poppers just doesn't have the will to
fight as much as they have motivation to jack their jaws. Many of the
right wing reports pine about how slow out of the gate this challenge
came, and how much foot dragging went on to take on a weak, Democratic
opponent. Most of those same reports offered the prospect of a
Supreme Court challenge, instead these ladies faded onto their silk
moire chaise lounges.

Try propagation modelers. VOACAP has been around for a good 10 years
now, with recent upgrade to VOAWIN.

The better question is could you even hope to achieve this little?
Aside from having your own antenna farm, DX is a spin of the wheel and
most simply try.

Perhaps you should use the propagation modeler to investigate the
range of variation of DX paths and heights associated with what you
can throw into the air.

625. Re: Correct Antenna Takeoff Angle?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-08 04:08:51 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <11acrqn3l7rt5ce@corp.supernews.com>
Source record: 75491

A number of propagation programs can tell you what angle you need. One that's easy to use, reasonably accurate, and free is W6ELProp, available from http://www.qsl.net/w6elprop/.

The ideal height for the antenna is a fairly easy geometry problem, but it's easiest to let a program tell you this, too. There are a number of antenna modeling programs available, some of which are free, and all will give very accurate results. Because it's my product, I recommend the free demo version of EZNEC from http://eznec.com, which is entirely adequate for this purpose. But any number of other programs would be suitable also.

One bit of advice -- don't get hung up on the "takeoff angle" reported by some antenna analysis programs (like EZNEC). It simply means the angle at which the pattern is maximum, and isn't important for this or most situations. What counts is the field strength or gain at the angle which you'll be using for communication -- that's the angle reported by the propagation program. That's the number you want to maximize.

If the motor home isn't rolling down the road, try a quad :-)
If the motor home is rolling - better lower it at the underpasses.
OR one of those little magnetic loops.
-- and I think I recall someone on this group supporting something called a Fractenna, which sounds "groundless" as well.

Roy, thank you so much for taking the time to respond. I am going to go play with W6ELProp right away.

I am a very happy EZNEC user... this is how I am finding out the elevation angle of the major lobe, and because it's easy to 'adjust' by varying the height of the antenna, especially at a Field Day site, I want to put it up to maximize coverage of the rest of the country.

Thanks again.

Regards,

Al W6LX

P.S. I should probably start a different thread to make this comment, but I am still trying to find a good analysis program to enable simulation of an balanced-line end-fed antenna, sometimes called a Zepp. This evidently is one tough problem to solve.

John wrote:
"Looking for any ideas on a "No Ground" HF antenna to mount in a motorhome."

John must want an antenna which needs no physical connection to the earth. Any balanced antenna requires no physical connection to the earth. Also, many unbalanced antennas have no physical connection to the earth but use the motorhome as a ground return for the antenna.

How about a screwdriver HF mobile antenna?

A wire suspended above the motorhome can turn it into a loop antenna. Phil Rand, W1DBM, now an SK, did this to his RV with good results which were published in QST and one of the ARRL Antenna Compendiums. I don`t remember which issues.

Why bother, unless you're having a problem with the heat? 20% loss is
just about exactly 1 dB.

That's 1 db I'd rather keep to myself...Why give it away if it's
not required? If you pump up the power, heat will likely be a
problem. But saying that, I'd rather avoid the tuner altogether...

I don't know of any program better than EZNEC for this. (Most others are just as capable.) You have to realize that the feedline is an integral part of the antenna, so it must of course be part of the model. Because it radiates, you have can't use the program's transmission line models, but have to include the feedline as wires. Depending on the length and orientation of the feedline, there might also be significant current flowing from the rig to the Earth via whatever path it can take, and this is also part of the antenna and must be included in the model if the model is going to predict the antenna performance.

Just becuase we call one part of the radiating system an "antenna", another a "feedline" and another "ground" doesn't give them magical properties and prevent them from radiating. All can be part of the radiating antenna system and, in the case of a Zepp, generally are.

The key here is the "Suggested layout" diagram in the .pdf file. The transmitter ground is connected to the ground plane, so the 50 ohm microstrip line is one conductor of the feedline and the upper surface of the ground plane is the other. There will be very little radiation from the feedline because return current will flow on the ground plane directly beneath the top side trace.

Right at the antenna is the only place where the microstrip line will physically move away from the ground plane -- the other conductor of the feedline. So only that part will radiate. Typically, you'd have a conductor which goes vertically straight up from the end of the microstrip line to the patch. Only that very short part of the feed system will radiate.

With mobile verticals what is ALWAYS forgotten about is that the car body is just as much a part of the radiating system as the antenna.

The body is just the lower half of a somewhat off-centre-fed, mishaped, vertical dipole.

It is ridiculous to describe its operation in such laymen's terms, but the body radiates as much useful power as the antenna itself. And it is fed with coax whereas, according to perfectionists, to prevent radiation from the feedline, it ought to be off-centre fed with 450-ohm ladderline. But from wherever it supposedly comes radiation is never wasted.

I've often thought of modelling a mobile loaded whip in a computer program. Input data would include body dimensions and height above ground. With a lot of patience you could do it with an EZNEC type of program.

Thanks for your reply. what about this patch antenna
http://rocky.digikey.com/WebLib/Toko/Web%20Data/DAK1575MS50T.pdf
it has a feed pin at the center, the ground is the whole area around
the pin , they say it has an adhesive tape for ease in mounting to the
ground plane , is this adhesive tape a good conductor so that it
connects the antenna ground to the circuit's ground or what? so,in the
pcb design should i make a rectangular copper area under this antenna
connected to the ground?

Whether you're violating the FCC's rules depends on what you mean by "terrible," and how "effective" you plan on making your transmitter. If you've got a transmitter that is designed to work in a car, and you want it to work at home, it's very likely that you can extend the transmit range to cover the area of your house without breaking any rules. If you are talking about setting up a little broadcast station for your neighborhood, well, that's a different story.

I don't know if the FCC requires type acceptance (in other words, prohibits you from tinkering with the transmitter by principle) for these fm wireless gadgets. This is the case with FRS; in particular, you're not allowed to crack open your radio and attach a quarter wave vertical. You might want to check on that, too.

You can mire through all of the FCC's rules on their web site. But I would still love to know if those fractal antennas work. :)

637. Elevated radial length?

I believe the length of buried radials is not that critical (bigger/more = better) and one size fits all bands. Within reason, subject to all the normal caveats, etc.

But what about elevated radials? Does anyone know Hustler's recommendation for elevated radials on their BTV series of verticals?

I suspect they want a pair of "tuned" radials on each band when elevated because that is what I have always seen. I am curious what Hustler says and what the group opines.

the more and the longer the better of course! the perfect situation is an infinite perfectly conducting plane. failing that it is up to you to figure out how much wire you can suspend and how long you can make it. keep in mind that the highest current density for the return currents (and hence the most chance for losses) is near the base of the vertical, so a good screen in close is a good investment. under my 80m elevated 4-square i have one elevated radial that is 1/4 wave, but then under it on the ground i have 150' of 4' wide 2x4 galvanized fence in a cross pattern (100' from the center of the 4-square radially out under each vertical then a 50' piece at 90 degrees to that one under each vertical.). under my 160m raised inverted L's i have 8 radials that are about 1/4 wave long. both of these work well, though if i was being a perfectionist and thought i could keep more wire in the air i would add more.

"But what about elevated radials?"

Just like 1/2 of an elevated center-fed dipole, the element length should be 1/4 wavelength for resonance with the other element(s). The open-circuit at the far end appears at the feedpoint as a low impedance.

Making the assumption that the "built-in FM transmitter" is the FM broadcast band and the device falls under the Part 15 unlicensed emitter rules, the FCC does not allow tampering with the antenna. To wit:

[Code of Federal Regulations]
[Title 47, Volume 1]
[Revised as of October 1, 2004]
From the U.S. Government Printing Office via GPO Access
[CITE: 47CFR15.203]

[Page 805]

TITLE 47--TELECOMMUNICATION

CHAPTER I--FEDERAL COMMUNICATIONS COMMISSION

PART 15_RADIO FREQUENCY DEVICES--Table of Contents

Subpart C_Intentional Radiators

Sec. 15.203 Antenna requirement.

An intentional radiator shall be designed to ensure that no antenna other than that furnished by the responsible party shall be used with the device. The use of a permanently attached antenna or of an antenna that uses a unique coupling to the intentional radiator shall be considered sufficient to comply with the provisions of this section. The manufacturer may design the unit so that a broken antenna can be

replaced by the user, but the use of a standard antenna jack or electrical connector is prohibited. This requirement does not apply to carrier current devices or to devices operated under the provisions of Sec. 15.211, Sec. 15.213, Sec. 15.217, Sec. 15.219, or Sec. 15.221. Further, this requirement does not apply to intentional radiators that must be professionally installed, such as perimeter protection systems and some field disturbance sensors, or to other intentional radiators which, in accordance with Sec. 15.31(d), must be measured at the installation site. However, the installer shall be responsible for ensuring that the proper antenna is employed so that the limits in this part are not exceeded.

[54 FR 17714, Apr. 25, 1989, as amended at 55 FR 28762, July 13, 1990]

Al Lorona wrote:
"How does one determine the correct antenna takeoff angle to communicate over a certain sistance?"

Solve the trigonometry / geometry problem involving the target distance and height of the reflecting layer.

King, Mimno and Wing in "Transmission Lines, Antennas, and Wave Guides"say:
Elevation angles above 3-degrees are useful because they are not immediately absorbed by earth loss. Low-angle radiation (above 3-degrees) makes a long distance trip to a distant receiver with the fewest hops or bounces between the ionosphere and earth. At 3-degree elevation, the distance per hop is about 3.500 km (2.100 miles). longer distances are automatically broken up into units not exceeding 3.500 km. Multipath transmission often exists and causes fading.

For distances less than 3,500 km, elevation angles of more than 3-degrees must be used. Often the antenna radiates a broad vertical pattern. In any case, the useful ray becomes steeper as the receiver becomes closer to the transmitter.

Kraus in edition No. 3 of "Antennas" shows how earth reflection affects the pattern and impedance of a horizontal antenna. At 1/2-wavelength elevation, the antenna has maximum radiation at 30-degrees over perfect earth and the center-fed 1/2-wave horizontal dipole has a feedpoint of 73 ohms. The Zepp should have about the same vertical maximum radiation angle but its impedance is something else.

Elevation angle is an inverse function of antenna height.

Best regards, Richard Harrison, KB5WZI

Just to add a little to Richard's quite correct advice.

A single well-elevated 1/4-wave radial has a resistive input impedance of very roughly 25 ohms. It is, in effect, a horizontal 1/4-wave antenna and forms, with a 1/4-wave vertical, a bent half-wave dipole which will radiate just as efficiently as a straight wholely vertical dipole. The radiation pattern, of course, will be different.

With two or more equi-distributed radials the radiation pattern changes again and the resistive impedance presented to the base of the antenna reduces still further.

When the height of radials above ground is of the order of 1/10th of their length the resonant length begins to decrease. So when the radials are lying on the surface of the ground the propagation velocity is about only half of the free space value. Consequently, to maintain the 1/4-wave resonant length, their physical length should be reduced.

On the other hand, when the radials are lying on the ground surface, ground loss damps down resonance and dimensions are no longer very critical. A collection of surface radials can be of various lengths. They can be investigated/selected by using a hand-held antenna analyser.

Shallow-buried radials, in average sorts of soils, are practically non-resonant and their lengths can be reduced without detriment to small fractions of the free-space wavelength.

The attenuation at HF along buried radials is quite high. There is not much point in having radials longer than the distance at which very little current is flowing in them.

For the behaviour of buried radials in various soils see program RADIALS2 from website below.

I gave you a break. The whole lot of it is nothing but Scattering parameters. Might be fine for SHF and above. Useless for mobile matching at HF. As predicted I couldn't understand one line of it. I doubt if anybody except the several authors have ever worked right through it. Have you? (2 smileys).

It's mid-day here. There's not a drop of wine in the house.

Your old pal, Reg.

Thanks for the encouragement and antenna.

I have two dipoles up right now. One is a 20 meter mono-bander that
was setup specifically for 20 meters and to test a test design for a
PVC 'cobra head' (whatever the generic name).

The other is a piece made of junk that I put up using parts I already
had available. (#14 electrical wire, PVC insulators and TV Coax). It
started as a 20 meter dipole, I added 40 and then 80 meters. It
wasn't supposed to be anything but a temporary antenna until I made a
new one, but weather, timing and money won't cooperate with me. I
have patched and patched it. Ice tore down one leg this winter and
destroyed half the PVC insulators I was using for spacers. Yesterday I
rewired the PL-259, cut the connection to the wires and re-wired it
and cut off the 40 and 20 meter elements. It tunes and hears much
better now.

I have always wanted antennas that would cover all bands without a
tuner. This was practical as a novice when all I could work was 80,
40, 15, and 10 meters. Three parallel dipoles hanging from one
antenna feed worked well. When I advanced to General, I used two
parallel dipoles and an antenna switch. (CW: 80, 40-15, 20, &10; and
SSB: 75, 40, & 10).

Today, my idea isn't as practical as it was. I now have a rig that
covers 160-6 meters on one HF connector. That's eleven bands!!
That's a lot of parallel dipoles on a feed even with the bands split
up into two antennas.

I acquired an antenna tuner recently and it tunes very quickly. I
still don't like it, but I can operate anywhere from 160-6 meters on

it (not that I have heard anyone on 6 yet.)

I would like to build a portable antenna using 300 ohm TV- twin lead
for the feed for the tuner. Is there a recommended length and feed
point for all bands?

Thanks

Buck

Dave wrote:
"The more and longer the better of course!"

Increases cost and wind loading.

If the ground plane is high above the earth, it isn`t required to hide the earth from the radiator to prevent displacement current flow loss in the earth.

If I recall the story, George Brown, the inventor of the ground plane antenna wanted to use only two opposing 1/4-wave radials in his antenna, but was persuaded by the RCA marketing department to use four.

The extent of the ground plane affects the radiation pattern. See Figure 21-10 on page 720 of the 3rd edition of "Antennas" by Kraus.

The imnfinite ground plane (soild line) has its maximum radiation at zero-degrees or toward the horizon. !/2-wave radials (dotted line) produces a slight elevation above the horizontal, but there`s not much difference in field strength at the angle if the ground plane is infinite or has 1/2-wave radials.

If you were a medium wave broadcaster, you would want the infinite ground plane. Brown, Lewis and Epstein at RCA determined the number of ground radials needed for very high efficiency long ago.

Best regards, Richard Harrison, KB5WZI

I can send you a copy of a program I wrote. It is based on Cecil's work. You can put in the length of the dipole you want to use, the frequency, and type of feed line. It gives you the choice of giving you the length of feedline for that single case, or a start and stop frequency in which case it prints out a chart of frequency vs. total length.Add jumpers to make up the difference above 80 feet and your good to go!

For portable operation a 130 foot dipole fed with 80 feet of 300 Ohm to a small piece of Plexiglas and two sets of banana jacks would allow you to put jumpers of various lengths into the jacks. The second set goes to the rig via a convenient length of 50 ohm coax with a choke balun of ferrites. Lengths of 1,2,4, and 8 foot would allow you to make up jumpers to enable 75 meters from 3.8 to 4 and all the other bands with the exception of 60 meters.

It can be made smaller if your only interested in 40 and up etc. Easy to carry, no tuner and worst swr around 1.7:1

For example a 2 foot jumper would put you at 4.0, and a series of an 8,2, and 1 jumper for 3.8

>productive, isn't it?

My IC-706 MKII says it starts reducing power "about" 2:1 SWR. However, it actually starts at somewhere between 1.3:1 and 2:1 depending on the band you are operating. I wouldn't use a tuner at 1.5:1 just to trim an antenna, i would just trim the antenna and not worry about it.

I have a tuner, a TT 247. It is a good tuner and tunes quickly. However, I really don't like tuners. To me there are three uses for a tuner, 1) emergency use with a makeshift antenna (or field antenna, etc.), 2) making a coral reef, and 3) not being able to have my antenna of choice for each band.

Dave C wrote:
"Skin back how far on the ends of the coax?"

I suspect the idea was to make a quick coaxial fipole at each end of the coax.

One removes 1/4-wave of the plastic jacket at each end. Then one carefully pulls the coax metal braid back over the remaining jacket as far as it will go. You now have a coax 1/2-wave center-fed dipole at the end of the coax where completed.

With a 1/2-wave dipole in a high-signal area directly connected to a 1/2-wave antenna in a low-signal area, energy is transferred from high to low. Try it. It is cheap and it may work.

I know I'll be corrected if I am wrong, but if I am correct, the SWR
is high (actually varies by band) on the feedline for the G5RV. The
twin lead portion doesn't have the losses the coax does with that SWR
so more of the signal gets to the antenna than it would if it were
just coax going to a twenty meter dipole.

"Useless" only in the sense of being unnecessarily complicated and
inconvenient to use. But not incorrect!

ALL valid methods will give the same correct result, if they are applied
correctly. That's how we confirm that a method is valid - by checking
its results for a series of test problems that can be solved by other
methods too.

Roy has posed a test problem that is very easy to understand, and can be
solved unambiguously by simple arithmetic. Solving it using S-parameters
will take time and some depth of understanding, but we can be confident
that they WILL give exactly the same result in the end.

The challenge for Cecil is to make his own theory do the same.

I have read several articles that show how this antenna works. The
450 ohm twin lead matches the antenna by wavelength (or some fraction
thereof.) I am wondering if this same concept can be successfully
used with 300 ohm tv twin lead.

It would be interesting to know if some small contraption could be
made to carry one around for a portable operation successfully.

Just curious.

Pardon me while I learn from this discussion.

The 450 ohm antenna is designed to be tuned by using exactly 1/2
electrical wave lengths to match both the transmitter and antenna.
This should mean that any differing feedline should work equally as
well (except for the losses) if I am correct....

Thank you,

Is this the same program here: http://www.qsl.net/w5dxp/notuner.htm ?

I have been looking at this awhile and wonder if the SWR on 17 and 10
meters can be better tuned by adding an additional 1/2 foot section.

It probably doesn't matter at that SWR.

another question related to the antenna:

Do you think this would work? Instead of switching the lead in and
out, could the leads be tapped at each band according to the matched
setting? So that instead of a series of knife switches, a double-pole
multi-throw switch could be used to select a band or frequency for
use?

Thanks again, gears are turning in my head again...

Some people refer to mobile verticals as "short tuned counterpoises,
working with a large untuned radiator".

>I've often thought of modelling a mobile loaded whip in a computer
>program. Input data would include body dimensions and height above
>ground. With a lot of patience you could do it with an EZNEC type of
>program.

There are probably some not-quite-obvious gotchas to be considered.

I've observed that a significant number of vehicles (e.g. my Ford
Aerostar minivan) don't weld the body panels to the frame. Instead,
the side panels and roof are _glued_ to the framework using a
structural adhesive, and there's no DC connection at these points...
just a capacitive one (probably with high capacitive reactance).
There's DC continuity in some places, but not at all contact points.

Depending on how the vertical is grounded to the vehicle (to the
panels, to the frame, or to both), the RF "ground" currents are likely
to vary quite a bit.

Similar issues are likely to exist in recent-model cars which have a
lot of fiberglass or other composite-plastic panels and structure.

Sure, although the actual feedline lengths needed to achieve a match
will be different than would be the case using 450-ohm feedline.

>It would be interesting to know if some small contraption could be
>made to carry one around for a portable operation successfully.

No doubt. What one would need, I think, would be a set of different
pre-cut segments of feedline (binary powers-of-two multiples of 6",
perhaps - 6" 1' 2' 4' etc.), with preinstalled snap- or screw-together
connectors. Banana plugs/jacks might work but I'd be concerned that
the weight of the feedline might tend to pull 'em apart... something
with screws, bolts, alligator clips, etc. might work better. You
could keep each length of twinlead rolled up and labeled with its
length.

However, I think this might not work out as well in practice as you
might think. If you're operating portable, you'll probably be putting
up your antenna in locations you haven't operated before, with
unpredictable combinations of supports. Differences in the antenna
height, shape (flattop vs. inverted-V vs. bent-all-over-the-place
horror), length, and the influence of ground conductivity and nearby
objects are going to make the antenna's feedpoint impedance difficult
to predict, and thus you may find yourself needing to raise and lower
it several times, and try different combinations of feedline segments,
in order to get an acceptable match.

For multiband portable/emergency antenna use, I'd probably just go
with an as-long-as-practical wire doublet, enough 300-ohm twinlead to
reach the ground from the expected operating height, and a small
T-match tuner with a current balun on the output. Probably less
hassle, quicker to set up and operate, and it wouldn't necessarily
take up any more space than a collection of different-length twinlead
segments with their connectors.

665. Re: faraday cage apartment / cell phone

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-08 18:15:34 UTC
From: John Smith <assemblywizard@gmail.com>
Message-ID: <dBGpe.29$t56.1919105@news.sisna.com>
Source record: 75382

I was actually thinking of a pair of biquad antennas, each at opposite lengths of a run of coax--sufficient length to place one biquad outside at a favorable location to hit a cell tower.
This is an example of a biquad I am speaking of:
http://www.nec2.org/wlan.htm

Once you have assembled your parts, should be able to get one up and going in short time...

Warmest regards,
John

You might try an experiment. Temorarily disconnect the DVD player, and then
connect the VCR output to the TV A/V input. What you are doing now puts two
sets of filters in tandem. If the A/V input plays better, you can get an A/V
2 way switch to select between the DVD player and VCR.

Is there some reson you don't just have the VCR in pass through mode, and
tune with the TV? Unfortunately, I am doing what you are, except that it is
through the AV input, because the tuner in the TV does not work. The picture
is not as good as it was with the TV tuner, probably because the VCR has
less bandwidth, even though it is a JVC Super VHS VCR.

Note that if you have some local stations, and some weak stations, you may
be overloading the preamp. Here in the US there is a problem with TV Channel

6, which is adjacent to the FM broadcast band

I don't want to say any more than I have to about this, I don't want to contaminate the answer. Lets just say 2 people disagree about something. I am trying to keep it simple.

Lets take for example a simple piece of coax. 1 center conductor, 1 outer braid. The cable is carrying AC in the RF range to an antenna. Why coax?

Do you think the outer braid could be correctly referred to as a "shield"?

Thanks,
--Dan

On Wed, 08 Jun 2005 12:52:01 -0400, Buck <iam@this.site> wrote:

>Pardon me while I learn from this discussion.

Hold on Buck.

So far there has been very little "learning" to be done from this discussion.

I dislike getting personal but I strongly suggest that you reject anything Fred has put forth. Some of what he says is correct, but for the most part you are being led astray. Since you don't yet have the skills to separate the good from the BS, the safest thing to do is ignore it all.

For example he has suggested that an all-band antenna can be nothing more than a 130' dipole fed through 100' of 450 ohm line to which you connect a 50 ohm coax and "your rig will be happy."

Let's examine this premise, shall we.

If you don't already have it, download the free version of EZNEC.

www.eznec.com

If you have MS Excel do the following. If you don't skip down below the dotted line.

Download the program XLZIZL.xls at:

http://www.qsl.net/ac6la/xlzizl.html

Using EZNEC set up a frequency sweep, for example 3.5 to 4.0 MHz in 50 KHz steps and check Microsmith Files as an output and give a file name ("80meter" for example)

"Build" the 130' long antenna in the wires menu, add a source in the middle and do the frequency sweep. (I used a height of 50' and 12 AWG wire)

Open xlzizl.xls and select the "ZIZL" worksheet if it isn't already active. "Press" the "Clear all freq..." button (near cell A25). Press the "Read file for Freq, R, X" button (near cell D25). Navigate to the file location where you specified the Microsmith files be located. The default is in the Smith subdirectory in the EZW directory. Select the file "80meter.gam" and open it.

The calculated data will populate the Frequency, R at load and X at load cells.

Press the "Refresh and show Smith" button (near cell I28). The Smith chart will open and display the calculated impedance data for the 130' antenna operated from 3.5 to 4.0 MHz.

Now we are going to add a transmission line. Select the "ZIZL" worksheet again and press the "Set via Dialog" button (near cell A34).

The "Network definition" window will open with "Element position 1" selected by default. Change it to "5". Under "Element type" select Transmission line.

Under "Qualifier" scroll the dropdown menu to either "Generic 450 ohm window" or if you more more realistic numbers you can select one of the Wireman Ladder line types. (Ignore "wet" ones.)

Mouse down to the "Element Value" area an type in "100" for the length and press the "Set This Element" button and then close the Network definition window.

Press the Refresh and show Smith Chart button and you will now see two traces, the original "load" data and the feedpoint data at the input to the 100' transmission line. If you know anything about Smith charts you will immediately notice that the match is worse at the input of the line than it was at the antenna. So much for the "magic" 100' length that Fred proposes.

Going back to the ZIZL sheet and looking in the "results" area you can see that at 3.5 MHz the SWR is 36:1. Without the "magic" 100' of ladderline, the SWR is 3:1.

You can repeat this exercise at different frequency ranges and see just how awful this idea is.

Let's continue...

Assume that your 50-ohm coax is 50' long. Go back to the Network "Set via Dialog" button. Accept the "1" default for Element Position and again select Transmission Line for Element Type. For Qualifier, let's use Belden 9258 (RG8X), although you can use what you use.

Set the length to 50' and press "Set this Element." Close the window.

Press the Refresh and show Smith button and you will now see three traces on the chart: the load, the impedance at the inut of the 450 ohm line and the impedance at the input of the 50 ohm line.

Return to the ZIZL sheet and under results note that the SWR at 3.5 MHz is down to "only" 17:1. This is what your rig is going to see. Also note that the network loss (the line loss) is over 3 dB.

Now just for giggles, let's take out the 100' of ladderline and make the whole 150' run out of RG8X. You can just highlight the cells "G34 through G36" and delete them and then select cell C36 and type in 150 and tab out. Press "F9" and see the new results.

The 3.5 MHz SWR is now 2.4:1 and the total network (line) loss is 1.2 dB. So replacing the "low loss" ladderline with "lossy" coax improved the match and lowered the loss.

I don't know how much of this "magic" I can stand.

****

If you don't have Excel there is a more labor intensive method that is just as accurate.

Go to

http://www.qsl.net/ac6la/tldetails.html

and download the program and open it.

Select a transmission line type, "Generic 450 ohm Window" for example. The line parameters will populate the boxes to the right. Under Set Frequency, type in 3.5.

Run EZNEC one frequency at a time, beginning with 3.5 MHz. Look at the source data and note the Impedance R and X values. Pay attention to the sign of X.

Copy these values to "R" and "X" in the TLdetails program. Remember the sign of X. For example I used R = 61, X = -64.

In the "results" area under "At Input" you can see the R and X values at the input and note that the SWR in the 450 ohm line is about 7:1 and in the 50 ohm feeder Fred would have you connecting at this point the SWR is as before ~36:1.

If you want to "add" the 50 ohm line, copy down the R and X at the input (132, -470) and enter them in the the R and X boxes above. Change the line type to Belden 9258 and the length to 50 feet and as above, the SWR at the input is ~17:1.

To summarize:

There are ample free tools to work these problems out without relying on bafflegab. You don't have to take my word or anyone else's; work the problem yourself and learn something while doing it.

Coax has a nice property. When used as directed, it carries RF on its
center conductor and on the inside of its outer braid/shield/conductor
(equal currents, opposite direction at any given point in the coax).
There is little or no RF current on the outside of the braid/shield,
and the EM fields created the current flow on the conductors are
confined to the inside of the coax.

This has a number of advantages. Very little of the RF escapes the
coax (there's a small amount of leakage for single-braid coax, less
for double-braid, and very little indeed for hardline). This reduces
the potential for RF interference to nearby devices. Very little
external RF can leak into the cable. Because the RF fields are
confined to the inside of the cable, you can route coax right next to
or through metal objects (pipes, other cables, chickenwire in a stucco
wall, etc.) without the presence of this metal affecting the RF. Coax
cables with a solid dielectric hold the center and outer conductors at
a consistent distance, which doesn't change very much when you bend
the coax (within reason), and this means that the cable doesn't tend
to suffer from severe impedance "bumps" when bent or coiled.

The convenience of coax does come at a price. The geometry and
physics of a concentric-conductors cable tends to require that the
cable have a relatively low characteristic impedance. This can result
in higher losses per foot, in some cases, than could be achieved using
various configurations of two- or four-conductor balanced line (given
appropriate impedance matching at both ends).

>Do you think the outer braid could be correctly referred to as a "shield"?

It's often referred to by that term. It's common to see coaxial
cables referred to as "double-shielded" or "quad-shielded". Sometimes
two layers of braid are used, sometimes two or more layers of braid
are interspersed with metal-foil or metallized-plastic-film layers.

If you really want fun, get involved in the discussions about the pros
and cons of various shield configurations for cables used in

multiple-frequency duplex operations (e.g. amateur-radio and other
repeater systems). Receiver desensitization, intermodulation and
noise from within the cable become... well, let's say "interesting"...
in those applications.

Thanks for the writeup.

So, does the braid actually SHIELD or is it a consistent way to ensure interference will cross both conductors? And along the same line of thought, from the signal point of view on the inside of the cable everything is kind of even because of the equal current-opposite direction? I am going to contaminate my simple question by saying that I feel the braid is almost incorrectly referred to as a shield-it is a functioning conductor necessary for the signal to pass.

Also, how about this, reverse the polarity of the AC signal on the input of the coax. Any difference on the performance of the cable? I mean, if its AC the "shield" is carrying the same AC that the center conductor is right? I know the world of RF is like black magic, I'm trying to keep this basic.

Any thoughts or comments are welcome.

THANKS!

>So, does the braid actually SHIELD or is it a consistent way to ensure
>interference will cross both conductors?

Yes.

It performs both functions. It actually does provide a shielding, due to the "skin effect" - RF resists flowing _through_ the body of a conductor, and prefers to flow along its surface. It's very difficult for RF to flow from the inner surface to the outer surface, as it would have to travel through the thickness of the outer conductor.

That's probably the stronger factor in the interference resistance of a coax. There's also some which comes from the symmetrical shape, I'd guess, but I don't think it's anywhere near as much of an issue.

> And along the same line of
>thought, from the signal point of view on the inside of the cable everything

Yup.

> I am going
>to contaminate my simple question by saying that I feel the braid is almost
>incorrectly referred to as a shield-it is a functioning conductor necessary
>for the signal to pass.

This is not an either-or sort of situation. In a single-shielded coax, the braid (or hardline) performs both functions. It's a fully-functioning conductor, and it also acts as a shield which confines the signal to the inside of the coax. It's a floor wax *and* a dessert topping!

Single-shielded cables can be somewhat "leaky" - the shielding efficiency is not 100% if the outer conductor is not a solid, unbroken surface. That's the reason why many cables are multiply-shielded... the fields/current that leak out through the inner shields are confined by the outer ones. In cables such as this, the inner shields/braids/foils will be carrying almost all of the RF current, and providing a lot of the shielding efficiency. The outer shields will be carrying very little RF current - almost the only thing that these outer shields do, is provide additional shielding.

At the other end of the spectrum are the so-called "leaky" coaxes,
which are deliberately designed with incomplete shields and which can
be counted on to "leak" a certain percentage of their RF energy out
into free space over a specific distance. These are often used to
couple RF into underground spaces (e.g. tunnels), along railroad
tracks, and so forth.

>Also, how about this, reverse the polarity of the AC signal on the input of
>the coax. Any difference on the performance of the cable? I mean, if its
>AC the "shield" is carrying the same AC that the center conductor is right?

As far as the behavior of a given length of coax (away from the ends)
is concerned, there's no difference at all. The RF is AC and has no
polarity.

The problem is that there should only be a 1 second lapse of time between the beginning of gozinta at 100 Joules/sec and the beginning of comezouta at 100 Joules/sec. At what point is the additional 2 seconds worth of energy fed into the system?

Dan,
Basically, the differrence between coax and shielded cable is that coax will
have a controlled characteritic impedance. Shielded wire will hava a
characteristc impedance, but it is not specified. Shielded wire is normally
terminated in an impedance that is orders of magnitude higher than the wire
impedance, and people who use it are more concerned about its capacitance in
PF/foot.

Chapter 6-2 shows the phase center of the NBS dual-dipole feed to be .25 wavelength behind the dipoles, and around the same for a quadloop feed.

I suspect the phase center for the biquad is something similar.

Hi, Richard,

Yeah, your reference sounds about right. On Roy's suggestion, I downloaded W6ELprop and was shocked to find what the elevation angles are for even moderate path lengths. For example, I ran the path from Albuquerque to Philadelphia and was amazed to find that the signal would have to leave the antenna and reflect from the F layer at a 4 degree angle!! That's darn near parallel to the reflecting surface! This is far, far lower than I had ever thought. Most antennas have radiation at this angle, of course, but it is usually way down from the main lobe.

Even for double-hop contacts, I believe that the angle was something like 8 or 10 degrees for that same path, but I don't remember exactly right now.

You cite that a 1/2-wave-high horizontal antenna has a maximum lobe at 30 degrees. Starting at Albuquerque, that 30 degrees will get you only to about Oklahoma City on the first hop. Again, this surprised me. Believe me, I am becoming disabused of my previous erroneous notions.

These numbers are all for 40 meters and below. If the horizontal antenna in question is operated on a higher frequency, there's no guarantee (if I am reading the data in W6ELprop correctly) that a 30 degree incident angle will be reflected at all.

I tend to grow jaded upon hearing east coast stations (I am in Los Angeles) on 40, but now I will appreciate the physics necessary to make such a thing possible.

I am also going to have to put up my Field Day antenna much, much higher than previously thought.

Regards,

Al W6LX

Don't know exactly what you are inferring but the editors of QEX
have seen the light, :-) even if at RF frequencies. Quite a few
sources from the field of optics indicate that the phenomenon is well
known in that field even if not well understood in the field of RF.

It is very simple physics, Jim. When two coherent EM waves of equal
amplitudes and opposite phases attempt to travel in the same direction
in the same path, they cancel each other in their original direction
of travel. This is explained under "total destructive interference"
in "Optics" by Hecht. Since the energy in the two waves cannot be
canceled, that energy goes somewhere else. In a transmission line,
there are only two directions. If two waves cancel in one direction,
their combined energy components head back in the only other direction.
Everyone has seen that light interference pattern with his/her own eyes
and some just never realized what was happening.

Here's an example. If you wade through it, you will be forced to admit
that the destructive interference/wave cancellation at the non-glare
surface 'A' causes a reversal in the direction of the reflected
irradiance. That, my friend, is a 100% re-reflection, just as Walter
Maxwell has been saying for decades. 'n' is the index of refraction:

```
n=1.0 | n=1.2222 | n=1.4938
Laser-------air-------|---1/4WL thin film---|---infinite glass----...
| |
A B
```

The reflection from surface 'A' is canceled by an equal magnitude
and opposite phase reflection from surface 'B'. The energy components
in those two canceled waves join the forward wave because energy
cannot be destroyed (even though that concept seems to have serious
consequences to your mental health :-). Here's a quote from the
following web page.

http://micro.magnet.fsu.edu/primer/java/scienceopticsu/interference/waveinteractions/index.html

ï¿½When two waves of equal amplitude and wavelength that are 180-degrees out of phase with each other meet, they are not actually annihilated. All of the photon energy present in these waves must somehow be recovered or redistributed in a new direction, according to the law of energy conservation ... Instead, upon meeting, the photons are redistributed to regions that permit constructive interference, so the effect should be considered as a redistribution of light waves and photon energy rather than the spontaneous construction or destruction of light.ï¿½

In an RF transmission line, since there are only two possible directions, the only ï¿½regions that permit constructive interferenceï¿½ and "redistribution in a new direction" at an impedance discontinuity is the opposite direction from the direction of destructive interference/wave cancellation.

The above laser example is virtually identical to the following:

RF XMTR--50 ohm coax--+--1/4WL 61 ohm coax--+--infinite 75 ohm coax

If we use a coherent laser beam, no coax is required, so the behavior of the actual EM waves is relatively easy to analyze.

The states with the highest crime rates are the states with the
strictest gun laws. The states with the lowest crime rates are
the states with the most liberal gun laws. Crime invariably
nosedives when concealed carry permits are issued. What's wrong
with the liberals? Why don't they want liberal gun laws?

You can string a straight piece of nylon/dacron rope from
one point to another and spiral the ladder-line using the
rope for support. Black tie wraps keep the ladder-line in
position. Another idea is to hang the ladder-line, accordion
style, under the eaves of your house.

> so more of the signal gets to the antenna than it would if it were
> just coax going to a twenty meter dipole.

Here are the 50 ohm SWRs at the 300 ohm twinlead to 50 ohm
coax junction that EZNEC produced in 2001 for a 102' dipole
at 40 feet fed with 27.7' of 300 ohm ladder-line.

3.8 MHz 3.2:1, 7.2 MHz 3.6:1, 10.125 MHz 56:1, 14.2 MHz 4.1
18.14 MHz 37:1, 21.3 MHz 11:1, 24.95 MHz 7.6:1, 28.4 MHz 66:1

The G5RV was designed for 80m, 40m, & 20m operation and on
those designed-for bands does a reasonable job. It works
pretty well on 12m. Less well on 15m. Terrible for 30m, 17m,
and 10m operation.

However, if you are willing to vary the length of the 300 ohm
(or 450 ohm) matching section, you can achieve a reasonable
match on any HF band.

It's not Roy's results that are flawed. It's his premises. If
one has a 100v source with a 50 ohm series impedance feeding
a 200 ohm resistor, Roy's results are perfect. But when we add
that 1/2WL of 200 ohm line, it changes things from a circuit
analysis to a distributed network analysis. Much more energy
is stored in the system, using the transmission line, than has
reached the load during steady-state. Roy tries to completely
ignore the stored energy and alleges that there is no energy in
the reflected waves. But there is *exactly* the same amount of
energy stored in the feedline as is required for the forward
waves and reflected waves to posssess the energy predicted by
the classical wave reflection model or an S-parameter analysis
or an analysis by Walter Maxwell of "Reflections" fame.

> The challenge for Cecil is to make his own theory do the same.

"My theory" gives the exact same results as an S-parameter analysis
or a classical wave reflection model analysis. That's why I know it's
correct. Roy's (and Dr. Best's) models give the correct results for
voltage and current but not for power/energy. Remember Dr. Best's
assertion that 75w + 8.33w = 133.33w? It's been four years since
I told him here on this newsgroup that was ridiculous and that
75w + 8.33w + 50w of constructive interference = 133.33w
He responded that no interference existed or was necessary. That
can be verified by accessing Google, summer 2001.

Interference is built into the S-parameter model and the classical
wave reflection model but a lot of RF people don't recognize it. Dr.
Best's term, 2*SQRT(P1)*SQRT(P2), is known in the field of optics as
the "interference term" but he didn't know that at the time of
publication of his QEX article.

Each installation will vary depending upon the surroundings. My 50
ohm SWR on 17m was 1.6:1 and 1.7:1 on 10m. Those were acceptable
to my IC-706 at the time - even more acceptable to me now that I
have an IC-756PRO with its internal tuner. :-)

In fact, one of the advantages/benefits of this matching method is
that it allows internal tuners to achieve perfect matches on all
HF bands - no external tuner necessary.

Cecil,

The Journal of Irreproducable Results is a hilarious journal that has had a number of interesting articles in it. One I remember had to do with Peanut Butter and the Three Stooges and the Precession of the Earth's Axis (someone correct me if I misremembered). I believe it has been referred to as Mad Magazine for Stephen Hawking.

Another had to do with a nice compression algorithm that eventually reduced the input to 1 bit, no matter the input, and since that bit was predictable as just a 1, we could eliminate that also.

> used with 300 ohm tv twin lead.

The 450 ohm ladder-line yields a 50 ohm SWR lower than 2:1 for all
SWRs on the 450 ohm line between 4.5:1 and 18:1. Most 450 ohm SWRs
fall into that range.

The 300 ohm twinlead yields a 50 ohm SWR lower than 2:1 for all
SWRs on the 300 ohm line between 3:1 and 12:1. So you can see that
the matching range is not as wide with 300 ohm line as with 450
ohm line.

600 ohm open-wire line yields a 50 ohm SWR lower than 2:1 for all
SWRs on the 600 ohm line between 6:1 and 24:1 so that range is
even wider.

> It would be interesting to know if some small contraption could be
> made to carry one around for a portable operation successfully.

I carry around 1, 2, 4, 8, & 16 foot lengths of 450 ohm line and
just plug them together with banana plugs to achieve a match
without a tuner.

Side-by-side coax can be used as balanced line. I often toyed with
the idea of having a box of side-by-side RG-62 coax (Z0=186 ohms)
connected to switches or relays. For 186 ohm feedline, any SWR
between 1.86:1 and 7.44:1 would yield a 50 ohm SWR of less than
2:1. But you can see the matching range would be pretty small.

What you are missing is that first piece of matching section
which can be any length less than 1/2WL. After that first
piece of matching section, you could indeed switch to a
different characteristic impedance. Congratulations, you
have just invented the G5RV. :-)

Nope, that won't work because it leaves unterminated stubs
in the transmission line system. You might be able to
predict their effect but I have never tried to do that.
It's rather like a bag of worms.

> comezouta at 100 Joules/sec. At what point is the additional 2 seconds
> worth of energy fed into the system?

During the power-on transient phase. The load rejects half the incident
power. To keep things simple, assume a very smart fast tuner. After
one second, the feedline will contain 100 joules. The load will have
accepted zero joules. After two seconds, the feedline will contain the
100 joules generated plus 50 joules rejected by the load and the load
will have accepted 50 joules. Already the feedline contains 150 joules
while the source is putting out 100 joules per second. After 'n'
seconds, the line contains 300 joules, 100 from the source and 200
rejected by the load during the power-on transient stage.

seconds forward energy reflected energy load power
1 100 0 0
2 100 50 50
3 150 50 50
4 150 75 75
5 175 75 75
6 175 87.5 87.5
7 187.5 87.5 87.5
8 187.5 93.75 93.75
9 193.75 93.75 93.75
10 193.75 96.875 96.875
n 200 100 100

After 10 seconds the source has output 1000 joules. The load
has accepted 709.375 joules. 290.625 joules are already stored
in the feedline on the way to 300 joules during steady-state.
This is simple classical reflection model stuff.

If a load in rejecting half its incident power, the steady-
state reflected power will equal the steady-state load
power. The steady-state forward power will be double
either one of those.

> . . .

Ah, the drift and misattribution has begun. I'll butt in just long enough to steer it back.

I made no premises, and have not made any statement about energy in reflected waves. I only reported currents and powers which I believe are correct. Nothing you or anyone has said has indicated otherwise. I do question the notion of bouncing waves of average power, and have specifically shown that H's statement about the source resistor absorbing all the reflected power, when its value is equal to the line impedance, is clearly false. (The "reflected power" is 18 watts; the resistor dissipates 8.) I haven't seen any coherent explanation of the observable currents and power dissipations that's consistent with the notion of bouncing current waves. Perhaps your dodging and hand-waving has convinced someone (the QEX editor?), but certainly not me.

It's not a 200 ohm line, it's a 50 ohm line. (I see that I neglected to state this when giving my example, and I apologize. But it can be inferred from the load resistance and SWR I stated.)

It baffles me how you think you can calculate the line's stored energy without knowing its time delay. The calculation of stored energy is

simple enough, but it requires knowledge of the line's time delay. A half wavelength line at 3.5 MHz will store twice as much energy as a half wavelength line at 7 MHz, all else being equal. Even if you knew the frequency (which I didn't specify), you'd also need to know the velocity factor to determine the time delay and therefore the stored energy. I'm afraid your methods of calculating stored energy are in error.

But if you think the stored energy is important and you find (by whatever calculation method you're using) that it's precisely the right value to support your interesting theory, modify the example by doubling the line length to one wavelength. The forward and reverse powers stay the same, power dissipation in source and load resistors stay the same, impedances stay the same -- there's no change at all to my analysis or any of the values I gave. But the energy stored in the line doubles. (Egad, I hope your stored energy calculation method isn't so bizarre that it allows doubling the line length without doubling the stored energy. But I guess I wouldn't be surprised.) So if the stored energy was precisely the right amount before, now it's too much by a factor of two. And if you find you like that amount of stored energy, double the line length again.

I can see why you avoid the professional publications.

Back in the good old days, I was the proud owner of a 1956 Corvette, one of only 3467 built and along with the '57s, the prettiest ones ever buit. (damn I wish I had that car back). As are all Corvettes, it was fiberglass.

The soft top was stored under a flip up hatch behind the seats and there were two toggle clamps that secured the rear of the top when it was up. These penetrated the hatch cover so that it was possible to snake a vertical whip through them. I used a 17" aluminum transcription disk (common in broadcast stations of the day) with the coating stripped off for a ground plane under the hatch.

Best DX using a Heathkit "Twoer" was from the driveway of a friend in Tempe, AZ back to another friend in Tucson; about 100 miles.

This wasn't long after QST magazine had breathlessly reported that the "difficult path" between Tucson and Phoenix had been bridged.

This is what I use Buck. Mine is a 132 foot dipole and I insert the lengths with Omron 4PDT relays controlled by 2 decimal thumbwheel switches.

I just added another relay that ties the two sides of the twinlead together and feeds the center conductor of the coax. I plan to use it on 160. I have not tested it yet because conditions have been so bad with storms every day this week.

No buck, the line is always longer than 1/2 wave. It is a matching section
from what is at the antenna to 50 ohms, and then 1/2 wave from that point.

Hmmm, and I'm not even british.....

;)

The G5RV is a twenty meter antenna, isn't it? It needs a tuner on all
other bands if I am not mistaken.

As an alternative to putting your Field Day antenna higher, consider finding a location that will enhance lower angle radiation. 10 dB improvement over flat ground isn't too hard to come by in hilly or mountainous terrain. The best program I've seen for determining this is TA (Terrain Analysis), a DOS program which I believe you can still get from its author, Brian Beezley, K6STI. Last I heard, he'll only take orders by mail.

I have the same general problem here in Oregon, perhaps even more so. My Field Day antennas and location are chosen as though I were after DX. You might be interested in the "Field Day Special", an antenna I've used for many years from here -- it might also be suitable for you. You can find the info at http://www.eznec.com/Amateur/Articles/.

Dave wrote:

[regarding elevated radials]

> the more and the longer the better of course! . . .

No, that's not true. The efficiency of a vertical antenna with elevated radials declines noticeably as radial length increases beyond quarter wave resonance. With half wavelength radials, the efficiency can be very poor, depending on soil conditions, the number of radials, and the height. Decreasing the radial length to less than a quarter wavelength doesn't generally hurt the efficiency much. I'd guess that the efficiency would peak again at 3/4 wavelength, but I haven't checked. It's easy to model with EZNEC or similar program, and you can get a fair evaluation of a system with a few radials using the free demo version.

I should mention that the resonant length of radials is shorter when close to the ground than it is in free space. This has to be considered when choosing elevated radial length, particularly if the radials aren't very high in terms of wavelength.

Many people have done it with EZNEC. At HF, all that's necessary is a pretty crude outline, except in the close vicinity of the antenna where currents can change more rapidly. At VHF and above a much finer wire grid model is necessary. But as others have pointed out, a lot of modern cars aren't covered by a solid metal shell. So it might be difficult for these cars to figure out just what external and internal metallic parts will be carrying the current and therefore need to be included in the model.

That (a single fat radial) might be a reasonable model if the antenna is mounted at one end of the vehicle. If it's at the center of the top, the antenna is more like an asymmetrical dipole, with the "antenna" being one half and the vehicle being a much fatter lower half. In that case the car will produce a substantial vertically polarized field -- perhaps more than the "antenna".

>with a silly answer, which is still quite welcome. Keep your BS to
>yourself, please.

Hi Tom,

If the contradiction didn't hit you yet, it was obvious that the
thread ended with my last post and out of boredom you chose to mix it
up with at least two more - yours then my response. Please don't
patronize us with insisting it would not be otherwise. Banning the
BS? Can you resist adding another example? ;-)

You know full well I respond to ALL interesting topics and any mawkish
sentimentality of appealing for injunctions against them to the "court
of public opinion" is best left to broadcast AM radio where they need
air-fill to sell laxatives.

Hello All,
I've justed moved into a new home and the XYL isn't crazy about my
plans to build my "dream tower" just yet. I was wondering how much
weight a push up telescopic mast such as the Rohn 50 foot guyed unit
could safely carry. Specifically I want to mount my MFJ 80-2 meter
vertical, which weighs in at 20 pounds, and an 80 meter dipole on a
side arm mount. Any thoughts from the group that meight prove helpfull
are welcome.
Thanks and 73,
Rob Brown

If it's well guyed and you keep it vertically straight it shold be OK
as far as the vertical is concerned. I'd be leery of hanging the 80M
dipole on a side arm because it would generate a torque load on the
mast which could cause problems. I'd forget the side arm and hang the
dipole on the mast as close as possible to a guy level. There might be
some issues with interactions between the vertical and the dipole on
80M.

That's exactly the false premise I am talking about, Roy. If you assume waves of reflected power don't exist, you will find a way to rationalize proof of that premise. You are looking under the streetlight where the light is better instead of in the dark spot where you lost your keys (keys being analogous to reflected power).

> It's not a 200 ohm line, it's a 50 ohm line. (I see that I neglected to
> state this when giving my example, and I apologize. But it can be
> inferred from the load resistance and SWR I stated.)

Yes, you are right about that. But one can visualize the interference by inserting 1WL of lossless 200 ohm feedline between the source and the 50 ohm line which changes virtually nothing outside of the 200 ohm line.

100v/50ohm source with 80v at the output terminals.

80v--1WL lossless 200 ohm line--+--1/2WL 50 ohm line--200 ohm load

The source sees the same impedance as before. The same impedance as before is seen looking back toward the source. Voltages, currents, and powers remain the same. But now the interference patterns are external to the source and can be easily analyzed.

> It baffles me how you think you can calculate the line's stored energy
> without knowing its time delay.

The time delay was given at one second, Roy. I really wish you would read my postings. Here is the quote from the earlier posting:

```
*****************************************************************
* If we make Roy's lossless 50 ohm feedline one second long (an *
* integer number of wavelengths), during steady-state, the source *
* will have supplied 68 joules of energy that has not reached the *
* load. That will continue throughout steady state. The 68 joules *
* of energy will be dissipated by the system during the power-off *
* transient state. *
*****************************************************************
```

I DIDN'T EVER TRY TO CALCULATE THE STORED ENERGY IN YOUR LINE. But a VF could be assumed for your lossless line and a delay calculated from the length. Or you can just scale my one second line down to a one microsecond line. The results will conceptually be the same. Of course, the one microsecond line would have to be defined as an integer number of half wavelengths but the frequency could be chosen for that result.

So 68 microjoules would be be stored in that one microsecond feedline, 50 microjoules in the forward wave and 18 microjoules in the reflected wave. The source is still supplying 32 microjoules per microsecond and there is exactly enough energy stored in the feedline to support the energy in the forward wave and reflected wave as predicted by the wave reflection model or S-parameter analysis.

> The calculation of stored energy is
> simple enough, but it requires knowledge of the line's time delay.

The time delay was given, Roy, at one second. See the above quote. That technique changes watts to joules. Buckets of joules are not as easy to hide as watts.

> A
> half wavelength line at 3.5 MHz will store twice as much energy as a
> half wavelength line at 7 MHz, all else being equal. Even if you knew
> the frequency (which I didn't specify), you'd also need to know the
> velocity factor to determine the time delay and therefore the stored
> energy. I'm afraid your methods of calculating stored energy are in error.

I'm afraid you don't read my postings. THE FREQUENCY AND VELOCITY FACTOR DO NOT MATTER WHEN THE FEEDLINE IS SPECIFIED TO BE ONE SECOND LONG. Wavelength and VF are automatically taken into account by the assumption of a one second long feedline. I have used that example before for that very reason. A one second long feedline is filled with joules. Joules are harder to sweep under the rug than watts are.

> But if you think the stored energy is important and you find (by
> whatever calculation method you're using) that it's precisely the right
> value to support your interesting theory, modify the example by doubling
> the line length to one wavelength. The forward and reverse powers stay
> the same, power dissipation in source and load resistors stay the same,
> impedances stay the same -- there's no change at all to my analysis or
> any of the values I gave. But the energy stored in the line doubles.
> (Egad, I hope your stored energy calculation method isn't so bizarre
> that it allows doubling the line length without doubling the stored
> energy. But I guess I wouldn't be surprised.)

If the forward power and reflected power remain the same, doubling the length of the feedline must necessarily double the amount of energy stored in the forward and reflected waves. That fact supports my side of the argument, not yours.

> So if the stored energy
> was precisely the right amount before, now it's too much by a factor of

> two. And if you find you like that amount of stored energy, double the
> line length again.

Feeble attempt at obfuscation. The amount of energy stored in a feedline
is proportional to its length assuming the same forward and reflected
power levels and assuming integer multiples of a wavelength. Again,
that supports my side of the argument 100% - and doesn't support yours.
It appears to me that you have just admitted your mistake but don't
realize it yet.

> I can see why you avoid the professional publications.

Actually, I have had a lot more articles published in professional
publications than I will ever have published in amateur publications.
I was an applications engineer for Intel for 13 years and professional
publication was required in the job description.

> The G5RV is a twenty meter antenna, isn't it? It needs a tuner on all
> other bands if I am not mistaken.

The G5RV needs a tuner on all bands. Acceptable SWRs are
very rare without a tuner. The G5RV is 1.5WL long on
20m. The resonant feedpoint impedance on 20m is in excess
of 100 ohms giving a 50 ohm SWR in excess of 2:1 so a
tuner is required, even on 20m. However, I have done to
a G5RV what Fred has done to a 1/2WL 80m dipole. The
matching section on my G5RV is a variable length between
22' and 38'. My G5RV has an SWR below 1.5:1 on all eight
HF bands. I'm going to write it up one of these days.

717. FM Antenna and Reception Problems

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-09 15:10:41 UTC
From: butlercellars <butlercellars@hotmail.com>
Message-ID: <TZYpe.10$W4.1016@okeanos.csu.net>
Source record: 75283

Our local cable company, Comcast, doesn't carry FM radio signals; therefore, I'm trying to improve my FM reception on my home receiver. I've had separate VHF and UHF antennas up for HDTV several years. They work wonders for HD and even analog TV, but the FM element on the VHF yagi surprisingly doesn't pick up much. Part of my problem is that I'm on an east facing hillside in the foothills directly north of one major metro market area and directly west of another. Despite that, I don't understand why I can get decent TV reception but no FM.

After limited success with a homebrew folded dipole, I picked up a high gain three element FM yagi. No matter where I seem to point it, I'm not getting any more signal strength than with the dipole on the back of the receiver. You'd think that aiming it east, southeast, or south towards all those transmitters would pull in something, but gain is very weak. However, if I point it northwest, at about 45 degrees up the hill behind me, I can actually pull in a few decent stations. Aiming the antenna in the opposite direction of the stations just seems contrary to logic. I understand that ground waves travel parallel to the earth, but could the signals be bouncing off the hillside too, acting like a huge reflector?

The thing that really gets me is that I can get excellent reception on all stations in my car sitting in the driveway, and driving around. Therefore, I'm thinking of dumping the yagi and trying to find or build a vertically polarized omni antenna. My car antenna does happen to be mounted at about 45 degrees. Any ideas on what might be going on, and how I might improve my reception? Any antenna designs and dimensions would be helpful. I guess worst case scenario is I can go down to the auto parts store, by a car antenna, and put it on my roof.

Please help. Many thanks!

-Bob

I am a little confused, so bare with me.....

I put up an antenna with 50 ohm of impedance. I feed it with any
length of 300 ohm feed less than 1/2 L. Then I run 1/2 L of 50 ohm
feed to the radio and I have the 50 ohm match?

similar:

I put up a 300 ohm antenna. I feed it with 300 ohm twin lead for less
than 1/2 L and 1/2 L of 50 ohm feedline. Is this a 50 ohm match?

(L=Lamda)

Thanks
Buck

721. Create Log Periodic

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-09 16:18:59 UTC
From: Rob Ramm <nospamtherammer@hotmail.com>
Message-ID: <1vpga1d7fd1vr45a8q2404r2ee08ej1h85@4ax.com>
Source record: 75287

I need some advice on a CLP5130-1 Log Peiodic made by Create.
I have had one of these mounted vertical on a fiberglass mast for 10 years now and it survived many windstorms until last week. It would have survived that one also if my 68ft selfsupport tower did not land on it :)

Anyways, what I intend to do is to repurchase a new one to mount vertical, and also another one to mount just below it horizontal for Television/FM reception. The one I use for scanning I feed with 5/8 hardline and I was intending on putting some Times microwave 75ohm hardline (1/2 inch) LMR 600-75 on the second one used for television,reduce it down to an F connector and put in a regular VHF/UHF preamp that adapts out to the "N' connector of the Create.

My question is, has anyone used these as a television antenna. I know they claim 10-12db gain across the whole band which is what my TV antenna boasted as well. I have seen posts that they do not really have as much gain as Create says, but then, does my Delhi Deep Fringe tv antenna which I have to replace also have the stated 7db gain on VHF lo and 13db gain on VHF-HI/UHF.

Looking at the specs, you would say, they should perform the same. I guess I am looking for some advice as to real world experiences since you cannot believe what is printed.
Do these work good as a tv antenna? You may say this is a bit extreme in cost. The wind loading on these antennas is stated around 1 square ft . Their relitively small "wind footprint" is attractive to me as I am looking for lighter alternative with both being at the top of a new 68ft tower I want to stay up.

Thanks,

Rob Ramm

Yes, very much so at this frequency. As in gold prospecting, the
signal is where you find it.

>The thing that really gets me is that I can get excellent reception on all
>stations in my car sitting in the driveway, and driving around. Therefore,
>I'm thinking of dumping the yagi and trying to find or build a vertically

This is more telling. It suggests that perhaps you haven't properly
connected either the antenna to the feeline, or the feedline to the
receiver, or yes the antenna is still not pointed in the right
direction - or you have a bum receiver. What about an FM portable
with a whip antenna? What about that FM portable with your antenna
feedline attached? If the whip works better, look at the feedline and
up.

Nope, 50 ohms is only one of an infinite number of impedances
you might encounter. For 50 ohms, you feed it with 1/2WL of
300 ohm feedline. This is similar to (but not exactly like)
a G5RV used on 20m.

> I put up a 300 ohm antenna. I feed it with 300 ohm twin lead for less
> than 1/2 L and 1/2 L of 50 ohm feedline. Is this a 50 ohm match?

Nope, you cannot transform the impedance of a 300 ohm antenna
using 300 ohm feedline. You need reflections to cause an
impedance transformation. A 300 ohm antenna impedance is
not within the green doughnut area below.

The range of impedances that can be matched with a length of
450 ohm ladder-line are represented by the green doughnut at:

http://www.qsl.net/w5dxp/smith.htm

The impedances outside the green area cannot be matched by
only one 450 ohm matching section. The area in the doughnut
hole cannot be matched by only one 450 ohm matching section.

ISRAELI SPIES and their viruses in U.S. and GERMAN computer systems

Trojan spyware suspects arrested as major industrial espionage scandal
emerges

by Bill Goodwin

Tuesday 7 June 2005

A London-based Israeli couple are at the centre of one of the world's
largest industrial espionage and computer hacking scandals.

Computer specialist Michael Haephrati and his wife Ruth are accused of
supplying the sophisticated Trojan horse software used by private
detective agencies to spy on scores of top global firms.

But police believe this is just the tip of the iceberg, and firms
worldwide, including those in the UK, may have had confidential
information compromised after being infected by spyware supplied by the
Haephratis.

The couple were remanded in custody after an appearance at Bow Street
Magistrates Court on 26 May and are now facing extradition to Israel.

Their arrest followed an international investigation by the computer crime unit of the Tel Aviv fraud squad, Interpol, police in Germany and the US, and the UK's National Hi-Tech Crime Unit.

Michael Haephrati, who has homes in London and Germany, provided his services through London-registered computer consultancy, Target Eye. The company lists its specialities as security, intelligence and spyware.

According to Israeli police, Haephrati, who honed his computer skills during his three-year military service with the Israeli army, charged $2,000 (1,100) a month to supply and maintain custom designed Trojan horse spy software.

The full extent of the industrial spying operation has yet to be discovered, Peal Liat, superintendent at Tel Aviv police headquarters, told Computer Weekly.

"Right now it is a very sophisticated investigation. We have something like 150 different computers that were taken by the investigators. Every computer they open, they discover more. Every day it gets us more companies that ordered the information and more companies that were infected," she said.

Israeli police are investigating the role of 15 senior executives from top Israeli companies, after they allegedly hired detective agencies to obtain confidential information from their competitors' computer systems.

Telecoms companies, advertising agencies and public relations firms are among more than 20 organisations known to have been targeted.

Twenty-two staff from Israel's three leading private investigation firms have been arrested. The son of one of the chief suspects, allegedly discovered deleting files after being interrogated by police, has also been arrested, and faces a hearing in a juvenile court.

The agencies are accused of conducting industrial espionage on a huge scale against scores of computers belonging to listed companies and private individuals, according to documents lodged at Tel Aviv Magistrates Court.

Further arrests are expected as Israeli police complete forensic analysis of the computers seized from the offices of private detective agencies, Israeli firms accused of spying on their competitors, and Haephrati's London company.

Police believe the net could extend beyond the borders of Israel and that Haephrati may have sold his services to investigative agencies in the UK, Germany and the US.

Haephrati is accused of offering Trojan software to detective agencies Modi'in Ezrahi, Krochmal Special Investigations and Pelosoff-Ballai.

The agencies used the software, which was delivered by e-mail or given to targets in the form of CD-Roms containing business software, to retrieve confidential material for their clients.

Their investigations ranged from gathering evidence of marital infidelity to obtaining copies of companies' takeover documents and confidential business plans for competitors.

The Trojan was highly sophisticated and capable of evading detection by anti-virus systems, said Liat.

"They were able to see everything, from e-mails to documents to information. And they were able to copy it and take it out. We think the Trojan had the ability to log keystrokes."

The Trojan sent images and documents to FTP servers in Israel, Germany and the US, court documents reveal.

"Top Israeli companies suspected of using illicit software to spy on US/UK and German governments and corporations"

June 6, 2005 JERUSALEM (AP) - It started out as a family feud. But a small-time computer break-in has erupted into Israel's biggest business scandal in decades, reaching into some of the country's powerful corporate suites and jolting the cozy world of the industrial elite. Top Israeli blue chip companies, including a high-tech giant that trades in New York, are suspected of using illicit surveillance software to steal information from their rivals and enemies.
The list of victims is equally impressive, ranging from a cigarette importer to the local operations of the Ace hardware chain and Hewlett-Packard Co. Even a well-known TV entertainment reporter is caught up in the affair, claiming hackers invaded his computer to get phone numbers of celebrities.
The investigation has shed an unflattering light on the Israeli business world, where cutthroat competition in a small market, high-tech sophistication and the secretive traditions of the army form a volatile mix.
The case is also attracting the attention of top security software makers. Software firms in the U.S. have been updating their products to defend against similar outbreaks.
Sever Plocker, a leading Israeli economic commentator, said the scandal could have "unpleasant consequences" for foreign investment.
"People don't like to invest in countries where companies do some very unethical things," he said. "I think it is bad for Israel, bad for the image of Israel and nothing to be proud about."
The Trojan Horse scandal, named after the monitoring software secretly planted on the corporate computers, has been front-page news since police lifted a gag order this week. Police say 22 people have been arrested, and more arrests are expected.
"It's getting bigger every day," said Nir Nateev, head of the police

computer and cyber crime department in Tel Aviv, who said some 100 computers have been confiscated. "In the end, there will be dozens (of companies) involved."
The burgeoning scandal has sent a shudder through the business world. The country's central bank chief, American economist Stanley Fischer, warned this week that the case could harm foreign investment.
Amir Barnea, a business professor at the Interdisciplinary Centre, a prestigious Israeli university, attributed the scandal to the hypercompetitive business atmosphere in a tiny market of seven million people.
"Unfortunately some managers may lose the distinction between a legitimate fight for survival and doing illegal acts," he said.
Others said the combination of Israel's high-tech culture, fine-tuned in secretive military units, and a penchant for independent thinking made the scandal inevitable. Some of the world's top computer security companies, including Check Point Software Technologies Ltd., are Israeli.
"If Israelis see a wall, they will try to break it," said TV commentator Motti Kirshenbaum. "It is a challenge to break a wall. Israelis don't say, 'There's a fence, let's respect it.' "

Laser Could Rival Energy From Sun's Center
By H. JOSEF HEBERT, Associated Press Writer
Sat May 21, 4:20 PM ET
http://haarp-microwave.tripod.com/haarp.html
Ed Moses talks of the "grand challenge" that has consumed him for the past five years, comparing it to trying to hit the strike zone with a baseball from 350 miles away or tossing a dime into a parking meter from 40 miles. "That's the precision we have to have," says Moses, the director of a high-energy physics adventure to produce the world's most

powerful laser - one that scientists hope will create in a laboratory the energy found at the center of the sun.
In a building the size of a football stadium, engineers have assembled the framework for a network of 192 laser beams, each traveling 1,000 feet to converge simultaneously on a target the size of a pencil eraser.
The trip will take one-thousandth of a second during which the light's energy is amplified many billions of times to create a brief laser pulse 1,000 times the electric generating power of the United States.

It really is an interesting theory. And I'm willing to concede on a certain point here. If we were to fit a curve to the data in your far right side column, what we have is a dispersion curve. That is a predictable phenomenon, most easily observable on long transmission lines. However as this is not actual data, an important column is missing. A column marked 'energy from source' is crucial to proving your point. Without running the experiment and taking the data we can't really know how much energy would be in any of the columns at any given time. When we assume what that energy might be, we run the risk of making an ass out of u and me. Well, mostly u. :-)

Good suggestions, but there are no problems with the receiver, feedline, or antenna. And I know exactly where the xmitter towers are, including degrees orientation. Topo maps indicate I'm in a pocket; however, I thought FM signals would be more forgiving, not VHF and UHF TV as is the case.

FM portable w/ built-in whip antenna, dipole, or feedline/yagi reception is still marginal. My boat FM radio w/short rubber ducky performs as well as the car, but I don't want to sit in them to listen to the radio. As I stated in my original post, my VHF antenna has 1/2 wave horizontal FM elements too. The antenna works great for TV, but not FM. There's just something about my terrain where 1/2 wave horizontal FM elements are ineffective. Therefore, I'd like to try a good vertical (semi-vertical) omni.

Hi Bob,

This would suggest there is enough signal, or those working receivers
are exceptional. Go to Radio Shack and invest in a signal booster.
Get an over the air amplifier rather than a line amplifier. If
there's a separate line for the FM, from the antenna, get a mast
mounted, line powered amplifier.

It is odd that all the FM stations would be solely vertical
polarization. This would explain the horizontal antenna deafness.
There is also the old real-estate saw of "location, location,
location" and as you offer, yours sucks (maybe). Sitting there in the
Napa valley, are you trying to hit Frisco?

Hi Bob,

I noticed I used the word "line" in two senses here that may confuse.
The first actually means a line distribution amplifier. This is
usually used to augment a homes cable load of too many TV sets. The
other sense is a transmission line powered amplifier mounted on the
mast just beneath the antenna. Power into the transmission line and
up to the amplifier is applied through a special unit down near the
receiver which handles keeping the DC separate from the RF.

Jim Kelley wrote:
> A column marked 'energy from source' is crucial to proving
> your point.

Jim, I was hoping you were capable of multiplying 100 joules/sec
by the number of seconds to get the total number of joules
delivered to the system over time by the source. My 1000 joules
after ten seconds is 100 joules/sec multiplied by ten seconds.
Is that math too difficult for you? :-)

Maybe you need a simpler example. Here it is:

100w SGCL source----one second long feedline----load

The SGCL source is a signal generator equipped with a circulator
and circulator load. The circulator load dissipates all the
reflected power incident upon the signal generator. The signal
generator outputs a constant 100 watts.

The load is chosen such that the power reflection coefficient
is equal to 0.5, i.e. half the power incident upon the load
is reflected and half accepted by the load.

This configuration reaches steady-state in 2+ seconds. After 2+
seconds, the forward wave contains 100 joules and the reflected
wave contains 50 joules. 50 watts is being dissipated by the
load and 50 watts is being dissipated by the circulator load.
The source has output 150 joules of energy that has not been
dissipated by the load or the circulator load. 150 joules is
exactly the amount of energy to support the energy levels of
the forward wave and the reflected wave.

What could be simpler than that if you really believe in the
conservation of energy principle?

>have as much gain as Create says, but then, does my Delhi Deep Fringe
>tv antenna which I have to replace also have the stated 7db gain on
>VHF lo and 13db gain on VHF-HI/UHF.

All of this is also specs-manship. For the TV antenna, this gain can
be found for some regions and not others; and they can still claim the
better figures. The TV UHF band is immense, but in reality very
little of it is actually populated. The FCC of the late 40's must
have thought 88 channels would be needed eventually. They were wrong,
several hundred channels selling hoop earrings 24 hours a day would
have been an appalling prospect back then, and Newton Minnow would
have foamed at the mouth sputtering "vast wasteland."

>Do these work good as a tv antenna? You may say this is a bit extreme
>in cost. The wind loading on these antennas is stated around 1 square
>ft . Their relitively small "wind footprint" is attractive to me

You might find another vendor that offers a smaller antenna that
covers LESS spectrum with as much or more gain for all of your
pursuits. LPDAs are quite easy to predict (although the doing is a
bear) and as they are flat responsive (this is a trade-off for lower
gain with having so many elements) they represent a good general
coverage average gain solution.

Try orienting your Yagi with the elements vertical like the car antenna
is.

Also try another receiver.

If you car radio picks up the stations in front of your house, you
should be able to get them with your receiver. If not, your
receiver, ant cable or ant are broke.

Our local cable company, Comcast, doesn't carry FM radio signals; therefore, I'm trying to improve my FM reception on my home receiver. I've had separate VHF and UHF antennas up for HDTV several years. They work wonders for HD and even analog TV, but the FM element on the VHF yagi surprisingly doesn't pick up much. Part of my problem is that I'm on an east facing hillside in the foothills directly north of one major metro market area and directly west of another. Despite that, I don't understand why I can get decent TV reception but no FM.

After limited success with a homebrew folded dipole, I picked up a high gain three element FM yagi. No matter where I seem to point it, I'm not getting any more signal strength than with the dipole on the back of the receiver. You'd think that aiming it east, southeast, or south towards all those transmitters would pull in something, but gain is very weak. However, if I point it northwest, at about 45 degrees up the hill behind me, I can actually pull in a few decent stations. Aiming the antenna in the opposite direction of the stations just seems contrary to logic. I understand that ground waves travel parallel to the earth, but could the signals be bouncing off the hillside too, acting like a huge reflector?

The thing that really gets me is that I can get excellent reception on all stations in my car sitting in the driveway, and driving around. Therefore, I'm thinking of dumping the yagi and trying to find or build a vertically polarized omni antenna. My car antenna does happen to be mounted at about 45 degrees. Any ideas on what might be going on, and how I might improve my reception? Any antenna designs and dimensions would be helpful. I guess worst case scenario is I can go down to the auto parts store, by a car antenna, and put it on my roof.

Please help. Many thanks!

-Bob

Hi OM,

Without becoming too exaggerated, almost anything will offer the same results. Even by being too exaggerated, there is barely any problem to anticipate. At some level, you achieve what is called linear loading which at the extreme would be all the wire formed up in a loose coil 1/10th the size of a normal antenna. This too would work, but you are bordering efficiency issues. However, if you could force it to tune, it would probably do just as well (ï¿½6dB, or the mythical S-Unit).

So the question becomes one of what is the continuum of performance?

As long as the wire is remote from structures and earth, excess up to a 25% of the total length of the element could wave in the breeze, or be folded back upon itself (without shorting) or follow any path you choose. Likewise you could zigzag the entire length to absorb that same 25% that would not fit otherwise. Take care that the arbitrary line at 25% is arrived at by no better choice at limiting it at 10% or 50%.

This problem has enough complexity, but not too much, that you could examine the variations by using the free form of EZNEC.

You can't match a 300 ohm antenna with 300 ohm line. A matching section relies on SWR (read reflections) to match.

once matched, any impeadence feed line may be used from the matched point as long as it is an electrical half wavelength or multiple at the frequency of interest.

The only difference will be the SWR on the line. Your rig would still see the SWR ar the match point.

Given an antenna that has 50 Ohms +J0, feed it with 50 ohm line and the swr for the system is 1:1, substitute a 1/2 wave of 450 ohm line and the antenna and the rig are both at 50 ohms. The SWR on the feedline is 450/50 or 9:1.

Look at the half wave of feedline as two back to back 1/4 wave matching sections. The SWR on the feedline is of no consequece as the losses are so low as not to have a practical effect.

Hi Richard,

It's because this is the first test I've posted that I've seen come back onto the screen, and also because I've entered numerous msgs that fail to send, with the error msg that the server unexpectedly disconnected.

This situation has gone on for a few weeks, until today I when tried it again, and for some strange reason it works. I have no clue to why my server disconnected unexpectedly every time until today.

On the other hand, in the 'agent.ini' file my pop address is still listed as pop.iag.net, which has been canceled. I have changed the address in the options menu to pop.1and 1, which I'm using.

Anyway, I'm pleased that it works again, and thank you for your concern.

Walt

:-) My contention is that it's too remedial. What you require is faith, not math. Is the source supposed to be a virtual fire hydrant of constant energy, or is it more like a real system? You seem to be assuming a constant 100 Joules per second input, regardless of the fact that the impedance the source sees is changing over the interval. That's not particularly realistic, hence a need for the empirical. But we could assume that the source is constant, and continue.

You have provided a lot of detail about where it all resides and in what proportions, but you still haven't shown how much energy a source would actually produce under such circumstances. Further, you're assuming that energy would move forward in a transmission line at a rate higher than the rate at which it is provided by the source. This is highly

speculative and suspect. What we know for sure is, once steady state is achieved, energy is absorbed by the load(s) at the same rate at which it is generated, all the energy from the source goes to the load(s). Given that, there's very little impetus to believe that there need be any more than one second's worth of energy held within a one second long transmission line. It is therefore reasonable to contend that in the first scenario, 100 Joules of energy is held within the transmission line as it propagates toward the load. And in this latest scenario, 50 Joules is heading toward the load, and 50 is in the path to the circulator for a total of 100 Joules stored within the one second long transmission line.

The way to prove that there's any greater surplus of energy held within the transmission line would be to make the energy vs. time measurements at each end of such a transmission line. Absent that, it's purposeful speculation.

Hm, I wasn't having any trouble analyzing the system without the 200 ohm line. Why do you have to make the system more complex in order to apply your theory? Looking back at previous postings, it appears that any time anyone presents a model that gives you difficulty, you simply modify it to suit yourself, and deflect the discussion. I'm not interested in whether you can explain your theories in models of your choice. What remains to be shown is whether you can do so for the extremely simple model I proposed. You might recall that the first example in my posting in response to H's claim did indeed have source resistor dissipation equal to the "reverse power" -- it's much easier to apply a defective theory if you're free to choose special cases that support it. A valid theory should be able to work on all models, unless you clearly give the boundaries of its validity and why it has those limitations.

I apologize for not having read your posting more carefully. When I get snowed or when the discussion deviates from the point in question, I do tend to not read the rest. Because the stored energy has nothing to do with what happens to the waves of bouncing average power in steady state, I did ignore your details about it. Double my line length and the waves of bouncing average power have the same values as before, although the stored energy has doubled.

>
> If the forward power and reflected power remain the same, doubling the
> length of the feedline must necessarily double the amount of energy
> stored in the forward and reflected waves. That fact supports my side
> of the argument, not yours.

I'm not sure what you think my side of the argument is. That a transmission line doesn't contain stored energy? Of course it does. (See below, where I calculate it using conventional wave mechanics.) I'm simply asking where your imaginary waves of bouncing average power go in a painfully simple steady state system.

Your argument is that there are waves of bouncing average power. I asked where they went in the simple circuit I described. Calculation of the energy stored in the line does nothing to explain it. All it does is create the necessary diversion to deflect the discussion from the fact that you don't know or at best have only a vague and general idea.

Here's a derivation of the energy stored in the line using conventional wave mechanics:

T is the time it takes a wave to traverse the line in one direction. The analysis begins at t = 0, with the line completely discharged, at which time the source is first turned on.

1. From time t = 0 to T, the impedance seen looking into the line is 50 ohms, so the 100 volt source sees 100 ohms. Source current = 1 amp, source is delivering 100 watts, source resistor is dissipating 50 watts, and load resistor is dissipating zero. Therefore the energy being put into the line is 100 - 50 = 50 watts * t.
2. From time t = T to 2T, all the conditions external to the line are the same as above, except that the load resistor is now dissipating 32 watts, so the net energy being put into the line from the source is 100 - 50 - 32 = 18 watts * (t - T).
3. After time = 2T, steady state occurs, with the conditions I gave originally. From that time onward, the power into the line equals the power out, so no additional energy is being stored.

It's obvious from the above that the energy stored in the line from 0 to T = 50 * T joules, and from T to 2T = 18 * T joules, for a total energy storage of 68 * T joules.

No bouncing waves of average power are required; this can be completely solved, as can all other transmission line problems, by looking at voltage and current waves, along with simple arithmetic. I didn't bother doing this earlier simply because it's irrelevant; it has nothing to do with steady state conditions any more than the DC charge on a capacitor has to do with an AC circuit analysis. The only reason it's important is that it provided you with yet another way to divert the discussion from the question of what happens to those imaginary waves of bouncing average power in the steady state.

In the steady state we've got energy stored in the line (of course), and 18 watts of "reverse power". 8 watts is being dissipated in the source resistor. We can store just as much or little energy in the line as we choose by changing its length; as long as the line remains an integral number of half wavelengths long, there's no change to the line's "forward power", "reverse power" or any external voltage, current, or power. In fact, if we choose a line length that's not an integral number of half wavelengths long, we change the dissipation in the source and load resistors without any change in the "forward power", "reverse power", or reflection coefficients at either end of the line.

Your postings indicate that in your mind you've completely explained where the bouncing waves of average power are going, what they do, and why. If I'm correct and this is indeed all you have to offer, I'll once again bow out. I look forward to a careful reading of the QEX article.

Some folks say to cut the vertical element to make for a better resonance on
ten meters. Don't do that. Leave it as is.

About all the three radials on the bottom due is possible decouple the
feedline a bit. It will work fine with or without.

Adjust the two rings almost all the way out and it should hit fine on ten
meters. The antenna works on 15 also with about a 1.5 to 1. I never tried
it on 12. I doubt it will do much below 15 meters.

OY VEY!!! WHAT ARE THE ISRAELIS DOING TO AMERICAN JEWS?

WE NEED DAMAGE CONTROL ASAP.

Thanks for trying to come to the aid of our nation.

AIPAC sucks. They are unsavory and sneaky and untrustworthy and
unworthy of even our contempt.

Put them on the blacklist, one and all.

The HAARP and the NIF are even more dangerous than AIPAC which just
> > planted a few Mossad spies into the Pentagon and they sold the secrets
> > stolen to Israeli high tech and EM weapons national industries there.

AIPAC spies in the Pentagon and White House
http://www.whatreallyhappened.com/motherofallscandals.html

http://www.rense.com/general56/supreb.htm
Lawrence Franklin the Arnold Benedict Israeli-American of Pentagon
Affairs
http://www.rense.com/general57/linkcon.htm

Yes. NIF and HAARP are run by the same Pentagon group.

Israeli Spying:
The Mother of all Scandals
Once again, Israel has been caught with spies at the highest levels of
the US Government.

At the heart of the investigation are two people who work at The
American Israel Public Affairs Committee (AIPAC), a powerful pro-Israel
lobby in Washington. The FBI investigation, headed up by Dave Szady,
has involved wiretaps, undercover surveillance and photography that CBS
News was told document the passing of classified information from the
mole, to the men at AIPAC, and on to the Israelis.

CBS sources say that last year the suspected spy, described as a
trusted analyst at the Pentagon, turned over a presidential directive
on U.S. policy toward Iran while it was, "in the draft phase when U.S.
policy-makers were still debating the policy." This put the Israelis,
according to one source, "inside the decision-making loop" so they
could "try to influence the outcome." [CBS News]

Once again Israel denies wrongdoing, or faced with incontrovertible evidence (in this case one of the spies has reportedly cooperated with the FBI) dismisses the spying with the claim that such spying is harmless, because Israel and the United States are such good friends.

Well, let us take a closer look at that idea of "harmless espionage" by recalling Israel's most famous failed spy, Jonathan Pollard.

Jonathan Pollard is an American of Jewish descent, born in Galveston Texas, who established a career as an intelligence analyst for the US Navy. There have been many theories offered as to why Pollard decided to betray his country of birth to the Jewish state, but that Pollard did betray his country of birth to Israel is beyond all doubt. Pollard's defense was that he did not spy so much against the United States, only that he spied for Israel, sending them documents that in his opinion the US should have shared with Israel anyway.

That it was never Pollards job to decide what documents Israel should have was apparently irrelevant. Pollard arrogated that authority to himself. From his position of trust within the US Navy, Pollard delivered over 1000 classified documents to Israel for which he was well paid. Included in those documents were the names of over 150 US agents in the Mideast, who were eventually "turned" into agents for Israel.

But by far the most egregious damage done by Pollard was to steal classified documents relating to the US Nuclear Deterrent relative to the USSR and send them to Israel. According to sources in the US State Department, Israel then turned around and traded those stolen nuclear secrets to the USSR in exchange for increased emigration quotas from the USSR to Israel. Other information that found its way from the US to Israel to the USSR resulted in the loss of American agents operating inside the USSR. Casper Weinberger, in his affidavit opposing a reduced sentence for Pollard, described the damage done to the United States thus, "[It is] difficult to conceive of a greater harm to national security than that caused by... Pollard's treasonous behavior."

This should end the suggestion that Israel's spies are harmless. They are not. The United States' nuclear deterrent cost an estimated five trillion taxpayer dollars during the 50s and 60s to build and maintain, and less than $100,000 for Pollard to undermine. Israel waited 13 years to admit Pollard had been spying for them, and now lobbies for his release, having granted him Israeli citizenship.

Pollard is hardly the only Israeli spy operating in the United States. He just had the misfortune to get caught. Here are just a few examples of the Israeli spy operations that have been detected.

1947. Information collected by the ADL in its spy operations on US citizens is used by the House Select Committee on Unamerican Activities. Subcommittee Chair Clare Hoffman dismisses the ADL's reports on suspected communists as "hearsay."

1950 John Davitt, former chief of the Justice Department's internal security section notes that the Israeli intelligence service is the second most active in the United States after the Soviets.

1954 A hidden microphone planted by the Israelis is discovered in the Office of the US Ambassador in Tel Aviv.

1956 Telephone taps are found connected to two telephones in the residence of the US military attaché in Tel Aviv.

1954 "The Lavon Affair". Israeli agents recruit Egyptian citizens of Jewish descent to bomb Western targets in Egypt, and plant evidence to frame Arabs, in an apparent attempt to upset US-Egyptian relations. Israeli defense minister Pinchas Lavon is eventually removed from office, though many think real responsibility lay with David Ben-Gurion.

1965 Israel apparently illegally obtains enriched uranium from NUMEC Corporation. (Washington Post, 6/5/86, Charles R. Babcock, "US an Intelligence Target of the Israelis, Officials Say.")

1967 Israel attacks the USS Liberty, an intelligence gathering vessel flying a US flag, killing 34 crew members. See "Assault on the Liberty," by James M. Ennes, Jr. (Random House). In 2004, Captain Ward Boston, Senior Legal Counsel for the Navy's Court of Inquiry into the attack swears under oath that President Lyndon Johnson ordered the investigation to conclude accident, even though the evidence indicates the attack was deliberate. Given the use by Israel of unmarked boats and planes, and the machine-gunning of USS Liberty's lifeboats, the most likely explanation is that USS Liberty was to be sunk with all hands, with evidence left to frame Egypt for the sinking. This would have dragged the US into the war on Israel's side.

1970 While working for Senator Henry "Scoop" Jackson, Richard Perle is caught by the FBI giving classified information to Israel. Nothing is done.

1978, Stephen Bryen, then a Senate Foreign Relations Committee staffer, is overheard in a DC hotel offering confidential documents to top Israeli military officials. Bryen obtains a lawyer, Nathan Lewin, and the case heads for the grand jury, but is mysteriously dropped. Bryen later goes to work for Richard Perle.

1979 Shin Beth [the Israeli internal security agency] tries to penetrate the US Consulate General in Jerusalem through a "Honey Trap", using a clerical employee who was having an affair with a Jerusalem girl.

1985 The New York Times reports the FBI is aware of at least a dozen incidents in which American officials transferred classified information to the Israelis, quoting [former Assistant Director of the F.B.I.] Mr. [Raymond] Wannal. The Justice Department does not prosecute.

1985 Richard Smyth, the owner of MILCO, is indicted on charges of smuggling nuclear timing devices to Israel (Washington Post, 10/31/86).

1987 April 24 Wall Street Journal headline: "Role of Israel in Iran-Contra Scandal Won't be Explored in Detail by Panels"

1992 The Wall Street Journal reports that Israeli agents apparently tried to steal Recon Optical Inc's top-secret airborne spy-camera system.

1992 Stephen Bryen, caught offering confidential documents to Israel in 1978, is serving on board of the pro-Israeli Jewish Institute for National Security Affairs while continuing as a paid consultant -- with security clearance -- on exports of sensitive US technology.

1992 "The Samson Option," by Seymour M. Hersh reports, "Illicitly obtained intelligence was flying so voluminously from LAKAM into Israeli intelligence that a special code name, JUMBO, was added to the security markings already on the documents. There were strict orders, Ari Ben-Menashe recalled: "Anything marked JUMBO was not supposed to be discussed with your American counterparts."

1993. The ADL is caught operating a massive spying operation on critics of Israel, Arab-Americans, the San Francisco Labor Council, ILWU Local 10, Oakland Educational Association, NAACP, Irish Northern Aid, International Indian Treaty Council, the Asian Law Caucus and the San Francisco police. Data collected was sent to Israel and in some cases to South Africa. Pressure from Jewish organizations forces the city to drop the criminal case, but the ADL settles a civil lawsuit for an undisclosed sum of cash.

1995 The Defense Investigative Service circulates a memo warning US military contractors that "Israel aggressively collects [US] military and industrial technology." The report stated that Israel obtains information using "ethnic targeting, financial aggrandizement, and identification and exploitation of individual frailties" of US citizens.

1996 A General Accounting Office report "Defense Industrial Security: Weaknesses in US Security Arrangements With Foreign-Owned Defense Contractors" found that according to intelligence sources "Country A" (identified by intelligence sources as Israel, Washington Times, 2/22/96) "conducts the most aggressive espionage operation against the United States of any US ally." The Jerusalem Post (8/30/96) quoted the report, "Classified military information and sensitive military technologies are high-priority targets for the intelligence agencies of this country." The report described "An espionage operation run by the intelligence organization responsible for collecting scientific and technologic information for [Israel] paid a US government employee to obtain US classified military intelligence documents." The Washington Report on Middle East Affairs (Shawn L. Twing, April 1996) noted that this was "a reference to the 1985 arrest of Jonathan Pollard, a civilian US naval intelligence analyst who provided Israel's LAKAM

[Office of Special Tasks] espionage agency an estimated 800,000 pages of classified US intelligence information."

The GAO report also noted that "Several citizens of [Israel] were caught in the United States stealing sensitive technology used in manufacturing artillery gun tubes."

1996 An Office of Naval Intelligence document, "Worldwide Challenges to Naval Strike Warfare" reported that "US technology has been acquired [by China] through Israel in the form of the Lavi fighter and possibly SAM [surface-to-air] missile technology." Jane's Defense Weekly (2/28/96) noted that "until now, the intelligence community has not openly confirmed the transfer of US technology [via Israel] to China." The report noted that this "represents a dramatic step forward for Chinese military aviation." (Flight International, 3/13/96)

1997 An Army mechanical engineer, David A. Tenenbaum, "inadvertently" gives classified military information on missile systems and armored vehicles to Israeli officials (New York Times, 2/20/97).

1997 The Washington Post reports US intelligence has intercepted a conversation in which two Israeli officials had discussed the possibility of getting a confidential letter that then-Secretary of State Warren Christopher had written to Palestinian leader Yasir Arafat. One of the Israelis, identified only as "Dov", had commented that they may get the letter from "Mega", the code name for Israel's top agent inside the United States.

1997 US ambassador to Israel, Martin Indyk, complains privately to the Israeli government about heavy-handed surveillance by Israeli intelligence agents.

1997 Israeli agents place a tap on Monica Lewinsky's phone at the Watergate and record phone sex sessions between her and President Bill Clinton. The Ken Starr report confirms that Clinton warned Lewinsky their conversations were being taped and ended the affair. At the same time, the FBI's hunt for "Mega" is called off.

2001 It is discovered that US drug agents' communications have been penetrated. Suspicion falls on two companies, AMDOCS and Comverse Infosys, both owned by Israelis. AMDOCS generates billing data for most US phone companies and is able to provide detailed logs of who is talking to whom. Comverse Infosys builds the tapping equipment used by law enforcement to eavesdrop on all American telephone calls, but suspicion forms that Comverse, which gets half of its research and development budget from the Israeli government, has built a back door into the system that is being exploited by Israeli intelligence and that the information gleaned on US drug interdiction efforts is finding its way to drug smugglers. The investigation by the FBI leads to the exposure of the largest foreign spy ring ever uncovered inside the United States, operated by Israel. Half of the suspected spies have been arrested when 9-11 happens. On 9-11, 5 Israelis are arrested for

dancing and cheering while the World Trade Towers collapse. Supposedly employed by Urban Moving Systems, the Israelis are caught with multiple passports and a lot of cash. Two of them are later revealed to be Mossad. As witness reports track the activity of the Israelis, it emerges that they were seen at Liberty Park at the time of the first impact, suggesting a foreknowledge of what was to come. The Israelis are interrogated, and then eventually sent back to Israel. The owner of the moving company used as a cover by the Mossad agents abandons his business and flees to Israel. The United States Government then classifies all of the evidence related to the Israeli agents and their connections to 9-11. All of this is reported to the public via a four part story on Fox News by Carl Cameron. Pressure from Jewish groups, primarily AIPAC, forces Fox News to remove the story from their website. Two hours prior to the 9-11 attacks, Odigo, an Israeli company with offices just a few blocks from the World Trade Towers, receives an advance warning via the internet. The manager of the New York Office provides the FBI with the IP address of the sender of the message, but the FBI does not follow up.

2001 The FBI is investigating 5 Israeli moving companies as possible fronts for Israeli intelligence.

2001 JDL's Irv Rubin arrested for planning to bomb a US Congressman. He dies before he can be brought to trial.

2002 The DEA issues a report that Israeli spies, posing as art students, have been trying to penetrate US Government offices.

2002 police near the Whidbey Island Naval Air Station in southern Washington State stop a suspicious truck and detain two Israelis, one of whom is illegally in the United States. The two men were driving at high speed in a Ryder rental truck, which they claimed had been used to "deliver furniture." The next day, police discovered traces of TNT and RDX military-grade plastic explosives inside the passenger cabin and on the steering wheel of the vehicle. The FBI then announces that the tests that showed explosives were "false positived" by cigarette smoke, a claim test experts say is ridiculous. Based on an alibi provided by a woman, the case is closed and the Israelis are handed over to INS to be sent back to Israel. One week later, the woman who provided the alibi vanishes.

2003 The Police Chief of Cloudcroft stops a truck speeding through a school zone. The drivers turn out to be Israelis with expired passports. Claiming to be movers, the truck contains junk furniture and several boxes. The Israelis are handed over to immigration. The contents of the boxers are not revealed to the public.

2003 Israel deploys assassination squads into other countries, including the United States. The US Government does not protest.

2004 Police near the Nuclear Fuel Services plant in Tennessee stop a truck after a three mile chase, during which the driver throws a bottle

containing a strange liquid from the cab. The drivers turn out to be Israelis using fake Ids. The FBI refuses to investigate and the Israelis are released.

2004 Two Israelis try to enter Kings Bay Naval Submarine Base, home to eight Trident submarines. The truck tests positive for explosives.

This brings us to the present scandal. Two years into an investigation of AIPAC's possible role as a spy front for Israel, Larry Franklin, a mid-level Pentagon Analyst is observed by the FBI giving classified information to two officials of AIPAC suspected of being Israeli spies. AIPAC hires lawyer Nathan Lewin to handle their legal defense, the same lawyer who defended suspected Israeli spy Stephen Bryen in 1978.

Larry Franklin worked in the Pentagon Office of Special Plans, run by Richard Perle, at the time Perle (who was caught giving classified information to Israel back in 1970) was insisting that Iraq was crawling with weapons of mass destruction requiring the United States to invade and conquer Iraq. There were no WMDs, of course, and Perle has dumped the blame for the "bad intelligence" on George Tenet. But what is known is that the Pentagon Office of Special Plans was coordinating with a similar group in Israel, in Ariel Sharon's office.

With two suspected Israeli spies (at least) inside the office from which the lies that launched the war in Iraq originated, it appears that the people of the United States are the victims of a deadly hoax, a hoax that started a war.

The leaking of the investigation of AIPAC to the media on August 28th, 2004 gave advance warning to other spies working with Franklin. The damage to the FBI's investigation was completed when United States Attorney General John Ashcroft ordered the FBI to stop all arrests in the case. Like the Stephen Bryen case and the hunt for "Mega", this latest spy scandal seems destined by officials who have their own secret allegiances to protect, barring a massive public outcry.

The organization at the heart of the latest spy investigation, AIPAC, wields tremendous influence over the US Congress. Through its members and affiliated PACs, AIPAC directs a huge flow of campaign cash in favor of, and occasionally against, Senators and Representatives solely on the basis of their willingness to support Israel. As an example, in 2002, U.S. Rep. Artur Davis, D-Birmingham received so much help from pro-Israeli pacs that 76% of his campaign budget came from OUTSIDE the state of Alabama, mostly from New York.

Let me repeat that. A Congressman AIPAC wanted elected received more money from pro-Israel groups outside his state than from his own constituents inside his state. Who is that Congressman going to be thinking of when he votes in Congress?

So here is the mother of all scandals.

For two years, the FBI has suspected AIPAC of spying for a foreign country, and for those two years (and for decades before) that group suspected of spying for Israel has been reshaping the US Congress for the benefit of a foreign government.

And THAT is the mother of all scandals.

Think about that as billions of your tax dollars flow to Israel while your roads and schools crumble and decay and services are cut.

Think about that as the coffins come home with your loved ones inside.

Think about that when you and a million of your fellow citizens march down the streets of America opposing wars built on lies and deceptions and wonder why the government just doesn't want to listen to you any more.

Jim Kelley wrote:
> You seem to be
> assuming a constant 100 Joules per second input, regardless of the fact
> that the impedance the source sees is changing over the interval.

It's a mental exercise, Jim. I told you it was equipped with
a very fast very smart autotuner. If you are cool with a one
second long lossless feedline, you should be cool with a
very fast very smart autotuner.

> You have provided a lot of detail about where it all resides and in what
> proportions, but you still haven't shown how much energy a source would
> actually produce under such circumstances.

It's too simple to mention. The signal generator is putting out a
constant 100 watts. Hint: multiply the watts (joules/sec) by the
number of seconds to get the total joules. Dimensional analysis
indicates the product will be joules.

> Further, you're assuming
> that energy would move forward in a transmission line at a rate higher
> than the rate at which it is provided by the source.

Nope, I'm not. All wave energy moves at the speed of light. You
are confused. 100 joules per second is headed toward the load.
50 joules per second is headed away from the load.

> This is highly speculative and suspect.

Easy to understand given your level of confusion. To get the forward
power, divide the load power by one minus the power reflection
coefficient. That's 50w/0.5 = 100 watts. That's how you calculate
forward power.

> ... there's very little impetus to believe that there need be any more
> than one second's worth of energy held within a one second long
> transmission line.

Jim, if you have 1.5 gallons in a tank with one gallon/sec flowing
in and one gallon/sec flowing out, how many gallons are in the tank?
You have to have enough energy in the feedline to support the
forward power and the reflected power. More or less than that
amount would violate the conservation of energy principle.

> It is therefore reasonable to contend that in the
> first scenario, 100 Joules of energy is held within the transmission
> line as it propagates toward the load.

Yes, half is headed into the load and half will be rejected by
the load.

> And in this latest scenario, 50 Joules is heading toward the load,

50 joules are destined for the load but 100 joules are heading
toward the load. Remember to get 50 watts into the load, you
must hit the load with 100 watts. 100 watts for one second is
100 joules, not 50.

> and 50 is in the path to the
> circulator for a total of 100 Joules stored within the one second long
> transmission line.

Your math or model or both are faulty. The forward power must
be 100 watts to get 50 into the load. Therefore, the forward
wave energy in a one second feedline is 100 joules. The reflected
wave energy is half of that. Therefore, there's 150 joules in
the feedline.

Roy Lewallen wrote:
> Hm, I wasn't having any trouble analyzing the system without the 200 ohm
> line.

Yes, you were, Roy. That's why your results didn't agree with
mine AND the wave reflection model analysis AND the S-parameter
analysis AND the conservation of energy principle AND the
conservation of momentum principle.

Those RF waves are virtually identical to a laser beam in free
space. Where do you store the reflected energy when the reflected
wave is a light beam? An RF reflected wave *IS* a light beam, just
at a low frequency.

> Why do you have to make the system more complex in order to apply
> your theory?

Why are you afraid of using the correct model in order to
achieve correct results? DISTRIBUTED NETWORK THEORY IS SIMPLY
MORE COMPLEX THAN LUMPED CIRCUIT THEORY AND FOR GOOD REASON. Your
lumped circuit theory will NOT solve distributed network problems.
You have already proved that more than once in the past.

> When I get snowed or when the discussion deviates from the point
> in question, I do tend to not read the rest.

How do you give yourself permission to assert that your adversary
is speaking gobbledygook when you have deliberately not read his
postings?

> Because the stored energy has nothing to do
> with what happens to the waves of bouncing average power in steady
> state, I did ignore your details about it.

This is your false premise in action. The "waves of bouncing
energy" exist precisely because of the stored energy. The
SWR circle impedance transformation depends upon those
"bounding waves". Take away the "bouncing waves" and the
feedline is incapable of transforming impedances.

> No bouncing waves of average power are required;

It logically directly follows that transmission lines are
incapable of transforming impedances and all transmission
lines are therefore matched. Reminds me of your point-sized
mobil loading coils. :-)

The wave energy emerges from the source traveling at the speed of
light. A principle of physics says the momentum in that generated
wave must be conserved. Exactly where does the momentum go when
you put the brakes on the wave energy and store it in your magic
transmission line? Where do you hide the wave momentum?

Please tell me which of the numbers I posted disagree with yours, and which numbers you got. Once again, mine are:

Power from the source = 40 watts
Power dissipated in the source resistor = 8 watts
Power dissipated in the load resistor = 32 watts
Line SWR = 4:1
Line "Forward power" = 50 watts
Line "Reverse power" = 18 watts

Those are the only results I posted. What results did you get which are different?

Cecil's results:

Power from the source =
Power dissipated in the source resistor =
Power dissipated in the load resistor =
Line SWR =
Line "Forward power" =
Line "Reverse power" =

I ran an antron I picked up at the dump here on 10 meters (guy beside me was throwing it away--just couldn't let him do that <grin>)... just recently, someone thought so much of it--they stole it off the tower!!! Used it on cb here too, two major interstates here and lots of truckers...

I replaced it with a 1/2 wave length of thinwall conduit and stainless whip for a ~16 foot length--it is fed with a gamma match and works better than the antron ever did... not as good as the antron on the chicken band though...

Warmest regards,
John

No problems with the gear. Someone in sci.engr.television.broadcast nailed it on the first try. There's a 99FM xmitter a couple miles to the SE of me, lower in elevation, right in the path of all the other stations - & right smack in the middle of the FM band. Pointing the yagi in the exact opposite direction yields the best results for all other stations.

I'm still looking for some vertical omni antenna designs. Sorry for any duplicate posts, my hotmail account isn't very reliable.

Wouldn't it go to the circulator load which must always be placed at the source in order to clearly illustrate what happens when a circulator isn't in place at the source?

Hello. I currently use a WSP255RS RCA 900Mhz transmitter

http://tinyurl.com/a6y5e

to send MP3s to a Sony Spiar Receiver.

http://tinyurl.com/8ayyg

The range of the RCA is 300'. I would like to know
if there is an easy way to slightly increase the range of transmission.

Is there a 900Mhz antenna amp or kit available to maximize range?

Would desoldering the flimpsy antenna and putting a thicker/longer
antenna increase range?

How about making a better antenna? Something like
http://www.shed.com/tutor/mr26ant.html.

Any ideas would be appreciated.

Sorry, I was asking about the simple example I posted (which doesn't have a circulator), not the problem posted by Cecil.

How does placing a circulator at the source illustrate what happens when it isn't in place? Isn't it possible to explain what happens to the "reverse power" without a circulator? If not, why not?

It's not your numbers, Roy, it's your premises that violate
the conservation of momentum principle among other principles
of physics. RF waves possesss momentum and that momentum MUST
be preserved. Your premises simply violate the conservation
of momentum principle. When you assert that the reflected
waves possess no energy and it is stored in some magic place
at sub-light speeds, you are in violation of the principles
of physics.

You can resolve all of this by telling us where the energy
is stored, besides in reflected waves, when we are dealing with
light in free space and no transmission line because exactly
the same thing happens with EM light waves as happens with
EM RF waves.

Yes, that's cute too.

>The range of the RCA is 300'.

Rather pretty good if you already get this (instead of simply being an advertising claim).

>I would like to know
>if there is an easy way to slightly increase the range of transmission.

Hmmm, yes. But there are reasons not to. "Slightly" falls slightly outside of good specification. Please state specifically what you need.

>Is there a 900Mhz antenna amp or kit available to maximize range?

Undoubtedly, just like the availability of porn, you can buy almost anything. Is it commercial and could you get it at Circuit City or Radio Shack? - afraid not. It has to do with that law thingy, and the FCC (black market answers most of this).

>Would desoldering the flimpsy antenna and putting a thicker/longer
>antenna increase range?

Depends on antenna design, which could mean thicker/longer wire, but thicker/longer wire is not the answer - it depends on antenna design (probably why you came here).

>How about making a better antenna? Something like
>http://www.shed.com/tutor/mr26ant.html.

Where the other posts were cute, this is gross. Now, that is not to mean like vulgar - simply too, too big.

Look at the antennas in the first two links, and compare to this last one. Even if you made it the right size (and it is in fact the wrong

size); then it wouldn't really bring anything to the table. It does answer the agenda of antenna design, but it is not an example of what you describe wanting.

A simple solution for "slightly" more range is to build two corner reflectors (google search keywords) at each end. Tin foil on cardboard conception models can answer many questions. Toss in an additional keyword, 900MHz, and you will probably find enough to work with.

It was a tongue-in-cheek reply, Roy. These problems always seem to end up with a circulator in them at some point - clearly illustrating what happens under entirely different circumstances. :-)

Bob Lay, w9dmk, could explain it but he's off on a camping trip.
I think the QEX editors can now explain it also. 18 watts is
rejected by the mismatched load. It was part of a forward wave
that contained energy and momentum. That energy and momentum
MUST be conserved according to the laws of physics. The reflected
wave heads back toward the source at the speed of light and part
is re-reflected as Pref2*rho^2. The remaining
Pref(1-rho^2) part engages with Pfor1*rho^2 in an equal
magnitude/opposite phase wave cancellation as explained by Walter
Maxwell on page 23-9 of "Reflections II". Since energy and momentum
cannot be cancelled, the two cancelled waves conserve energy and
momentum by heading back toward the load at the speed of light as
a re-reflection of energy which joins the forward wave energy.

When a Z0-match is in place at the source, everything is also clear
since zero reflected energy reaches the source. The Z0-match case,
using an antenna tuner, is the most likely case to be encountered
in ham radio. 100% of the reflected energy and momentum is re-reflected
back toward the load, just as Walter Maxwell has been saying as long
as I can remember.

This stuff is not new. It is explained in "Fields and Waves ..."
by Ramo and Whinnery, copyright 1950's.

Roy Lewallen wrote:
> Isn't it possible to explain what happens to the
> "reverse power" without a circulator?

It is certainly possible in a Z0-matched system where
zero reflected energy reaches the source and the source
is feeding its designed-for load. If no reflected energy
reaches the source, the source impedance doesn't matter,
except for efficiency, which doesn't affect the rest of
the system. A one ohm source providing 100v to a 50 ohm
load and a one megohm source providing 100v to a 50 ohm
load will result in identical external conditions when
driving a 50 ohm load.

The picture is not as clear when reflected current and
voltage are allowed to flow into the source. We usually
don't know what the source impedance is and that
certainly handicaps any analysis. Modern designers simply
resort to protection circuitry and don't worry about
the energy analysis. We do know that reflections reaching
the source are not benign.

Plenty of "illicit/illegal" stuff is available,ya just gotta know where
to look,and of course,many times it also depends on how you use such items.
Adding an antenna will probably violate part-15,but I doubt you'll get
any "heat" from doing it.

The circulator, lossless feedlines of unreasonable length,
Time Domain Reflectometers, TV ghosting, etc. are all tools
for illustration purposes. However, a Z0-matched system is
an ordinary configuration in ham radio and is easy to analyze
since no reflected energy is allowed to reach the source. The
conservation of energy and momentum rules dictate where the
energy must go in such a case. We can debate why the reflected
energy is 100% re-reflected but there is no question that it
is 100% re-reflected because none reaches the source and
there are only two directions in a transmission line.

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <11ai1vg2c3soq42@corp.supernews.com>
Source record: 75435

I've explained how I calculated how much energy is stored in the transmission line. The movement of energy within the line is complex; in the abbreviated analysis I've had time to do so far, it sloshes back and forth in regions within the line. It does not travel in waves of average power, bouncing back and forth, and believing so isn't necessary in order comply with energy conservation. Your view of power and energy is oversimplified, and it fails when you're pressed to explain what happens at the interface between the line and the outside world.

Momentum is conserved in mechanical elastic collisions, but not in inelastic ones, e.g., when energy is being extracted. I wouldn't begin to try to apply this to a transmission line, but I see it doesn't bother you. I understand and believe the fundamental principles of physics and thermodynamics -- I'm just careful not to misapply them.

rho at the source is zero; the source matches the transmission line Z0. So the "part" which is re-reflected is zero, by your calculations.

The remaining
> Pref(1-rho^2) part

(which is all of it, since none was re-reflected)

>engages with Pfor1*rho^2 in an equal
> magnitude/opposite phase wave cancellation as explained by Walter
> Maxwell on page 23-9 of "Reflections II".

That part of Walt's text is talking about voltage and current waves. I'm familiar, thanks, with how they interact. You're the one talking about waves of average power -- since none of the reverse power wave is re-reflected, what happens to it? Where does the power go? Out the source resistor? I believe you said that 11.52 watts of it did. What happened to the rest?

Since energy and momentum
> cannot be cancelled, the two cancelled waves conserve energy and
> momentum by heading back toward the load at the speed of light as
> a re-reflection of energy which joins the forward wave energy.

What two waves head back toward the load? None of the alleged reverse power wave is reflected, by your own calculation. Where did it go? What's the other "cancelled wave" and where did it come from? What's its magnitude?

Thanks for the explanation. When Cecil has difficulty explaining a circuit, he comes up with one which he can explain and tries to deflect the discussion to it. This happens over and over and over -- it's really a pain to try to keep steering the discussion back to the original circuit.

That leaves us with no one who claims to understand Cecil's "explanation" of my simple circuit. Except, I guess, one guy who's on vacation and some folks who don't read this newsgroup.

I've told all of my wives that I was a ham and they better get used to
it. My current (and permanent) wife and I spent two years shopping
for houses on acreage without deed restrictions before we bought here.
She was fine with that. Put up a 60' motorized free-standing crank-up
tower, trash that MFJ and put up a Christmas tree and enjoy yourself.
If this is an issue, find another wife :-)

But there's a Z0 match at the source in my example. Simple wave mechanics show that the initial traveling voltage and current waves reflect from the load, return to the source, and don't reflect any further -- steady state is reached after a single round trip. That's a Z0 source match. No circulator is required.

> The Z0-match case,

Walt's book mentions momentum? Where?

is re-reflected
> back toward the load, just as Walter Maxwell has been saying as long
> as I can remember.

Hm. You said earlier that 11.52 watts of the reverse power wave reached the source. In a posting a short while ago you said that none of it is re-reflected (since rho at the source = 0), and now you say it all is.

Guess that covers just about any possibility -- no matter how things come out, you can say you gave the right answer. You might consider tossing out a couple more just in case.

> This stuff is not new. It is explained in "Fields and Waves ..."

If you put the perfect voltage source and the source resistor into a box and label it "Source", you have a Source whose impedance perfectly matches the transmission line. It's a Z0-matched system.

The source impedance of my circuit is as simple as it can get. If you can't explain how it works, it reveals a deficiency of your theory; I can easily calculate the voltage, current, and power in any component at any moment of time. Without requiring bouncing waves of average power. Or a circulator.

From where to where at what speed? Sloshing sounds like a
violation of the conservation of momentum. What force changes
the direction of the slosh? How much efficiency is lost in
the energy required to change sloshing directions?

> It does not travel in waves of average
> power, bouncing back and forth, and believing so isn't necessary in
> order comply with energy conservation.

Nothing RF travels in waves of average power. Average power is
just our simplified shorthand way of dealing with it. The AC
voltage is equal to the RMS value at only two points in
the cycle. Sticking with instantaneous values for everything
AC would complicate things beyond belief.

The values of voltage in your chart were RMS (average) values.
You don't seem to have a problem dealing with RMS values of
voltages and currents. Why do you have a problem with average
power associated with those average RMS values of voltage and
current.

> Your view of power and energy is
> oversimplified, and it fails when you're pressed to explain what happens

What is located at that interface? Anybody is pressed to explain
things when the source impedance is unknown and cannot be measured.

Hecht, in "Optics" certainly applies it to EM waves. RF EM waves
differ from light waves only in frequency. Conservation of
momentum is a cornerstone of EM light physics and is included
in the rules of relativity.

Walt's text talks about RMS (average) voltage and current. When
you multiply RMS voltage by RMS current, you get average power.
V+*I+ = forward power, V+/I+ = Z0, (PV+)=(E+)x(H+)
V-*I- = reflected power, V-/I- = Z0, (PV-)=(E-)x(H-)

> -- since none of the reverse power wave is
> re-reflected, what happens to it?

On the contrary, it is 100% re-reflected by wave cancellation,
the fourth thing that can cause 100% re-reflection. Optical
engineers understand that. Most RF engineers don't. Adding
the one wavelength of lossless 200 ohm feedline reveals the
wave cancellation mechanism.

> What two waves head back toward the load? None of the alleged reverse
> power wave is reflected, by your own calculation.

Not my calculation. All of the reverse power wave is reflected
by wave cancellation at the source terminals. No reflected power
is dissipated in the source resistor. Therefore, it is all
reflected back toward the load. The one wavelength of 200 ohm
lossless feedline reveals exactly what happens.

Perhaps you mean "the quoted range is 300'". This will an absolute maximum in an open field, /not/ through the walls of a house.

> I would like to know
> if there is an easy way to slightly increase the range of transmission.
>
> Is there a 900MHz antenna amp or kit available to maximize range?

Forget amplifying it. The cheap (and pretty nasty) transmitter circuitry won't provide a /clean/ enough signal for amplification, and 900 MHz electronics isn't trivial - layout is /really/ crucial.

> Would desoldering the flimsy antenna and putting a thicker/longer
> antenna increase range?

Possibly. Try it and see.

> How about making a better antenna?

Possibly. Do a Google search for a suitable 900 MHz home brew antenna - perhaps a corner reflector type.

> Something like
> http://www.shed.com/tutor/mr26ant.html.

Definitely not. That's truly hideous, on the wrong frequency, and probably doesn't work at all - he'd be better off with a random length of wire! The "FM balun" he suggests would be seriously lossy at 900 MHz, and the dimensions are wrong.

Bob

> Z0 source match. No circulator is required.

You obviously don't understand a Z0-match, Roy. All the reflected
power is re-reflected back toward the load at a Z0-match. What you
have in your example is a Z0-match to 200 ohms. You can prove it
by observing that the reflections disappear on a piece of 200 ohm
feedline.

------200 ohm feedline---+---1/2WL 50 ohm feedline---200 ohm load

The SWR on the 50 ohm feedline is 4:1. The SWR on the 200 ohm
feedline is 1:1. That is a 200 ohm Z0-match and rho is 0.6

> Hm. You said earlier that 11.52 watts of the reverse power wave reached
> the source.

Reflected by wave cancellation *at* the source , certainly not
flowing back through the source. What I said is that the two 11.52
watt reflected wave components undergo wave cancellation that results
in 23.04 watts being re-reflected.

>In a posting a short while ago you said that none of it is
> re-reflected ...

Sorry, Roy, you know and I know that is a lie. Please
apologize and retract that false statement.

Roy Lewallen wrote:
> If you put the perfect voltage source and the source resistor into a box
> and label it "Source", you have a Source whose impedance perfectly
> matches the transmission line. It's a Z0-matched system.

Sorry, Roy, a 50 ohm source driving a 200 ohm load is NOT a
Z0-matched system by any stretch of the imagination. From the
ARRL Antenna Book: "The Z0 mismatch (at the load) creates a
reflection having a magnitude of rho = (ZL-Z0)/(ZL+Z0)
causing a reflection loss rho^2 that is referred back along
the line to the generator. This in tern causes the generator to
see the same magnitude of Z0 mismatch at the line input."

This exactly describes your example which has a 50 ohm Z0
mismatch (and a 200 ohm Z0 match). The mismatch is easy to
see in the following:

50 ohm source--1WL 200 ohm line--+--1/2WL 50 ohm line--200 ohm load

Point '+' is a Z0-match to 200 ohms. A Z0-match to 50 ohms
doesn't exist anywhere.

> The source impedance of my circuit is as simple as it can get. If you
> can't explain how it works, it reveals a deficiency of your theory;

You assume I don't know how it works because you don't even know
what a Z0-match is???????? How very typical of you.

Cecil imagines a circulator is a device that separates forward and
reflected waves of average power, because that is what Cecil's theory
says they must do.

In other words, Cecil's circulator is a device that takes a perfectly
straight-forward argument... and makes it circular.

Hi OM,

OK, another cute link. However, $30 and postage/handling does nothing
to add signal that wasn't already available from the existing design.
On the other hand, if you or your folks found comfort, years back, in
buying a pet rock, this could be your antenna.

>If this is an issue, find another wife :-)

Hooray for Linda, Wes, she's got her head on straight. My first wife, Harriette was one of George Sterling's assistants as Chief Eng of the FCC before I met her in 1940 at the FCC Allegan Primary Monitoring Station, where she worked after transferring from the Washington office. So she knew hams long before she and I met. I had been a ham for seven years before we met, so she knew what she was getting into and she encouraged me in every ham activity I wanted to get into.

Unknowing to us monitoring guys, she knew the code. We all had code oscillators at our work station, and we often made remarks across the room about her via cw. Little did we know that she copied all our remarks, and had some pretty sharp comebacks for us. It's not only due to my being a ham that all four of my kids are licensed, as well as my son-in-law. Harriette had a lot to do with it. My oldest son Bill, W2WM, is already retired, and has been licensed for 38 years.

Son Rick, WB4GNR, a computer engineer with Agilent, has also been licensed 38 years. Daughter Sue and her husband have been licensed for 25, but son John, K4JRM, has only been licensed for a little over a year.

I lost Harriette to emphysema in 1985, but in 1996 I found my first love, my high school sweetheart, after neither of us knew where each other was for 61 years. We married on the island of Anguilla in 1997, living in my home in DeLand, FL in winter and in her home in Mt. Pleasant MI in summer. Jean is an emeritus professor of speech at Central Michigan U, and also supports my hamming emphatically. She did all the proof reading of Reflections 2 prior to publication. Enough gab for now,

Walt, W2DU

784. Determining SWR and Transmission Line Losses ?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-10 07:33:21 UTC
From: Gary
Message-ID: <rqfia19kr6s5ttt1ms22uid30utfp7vvg9@4ax.com>
Source record: 75450

If, just for example I'm loading 20 meters into a 40 meter dipole what's the formula for determining the resultant SWR ? And then what's the formula for determining what my losses would be between say feeding the 40 meter dipole with 100' of RG-58 vs 100' of 450 ohm ladder line on 20 meters. Of course the 450 ohm twinlead would screw up the (likely) close match between the dipole and the RG-58 on 40 meters. Maybe this requires some kind of antenna modeling program ?

Thanks in advance.

Gary

Have you forgotten the corollary which states that invocation
of Nazism expressly for the purpose of terminating the argument is
invalid and does not terminate debate?

Similarly, just because it rains every time you wash your car,
you cannot invoke a rainy day by washing your car for that purpose.

Contrariwise, it can be proven that, while the phone may ring
every time you go into the bathroom, you can indeed force the phone to
ring at will just by entering the bathroom. Tubs work the same way.

I was wondering 2 things:

While on hf i have a current balun, thyre pretty common to help elmin
any bad signals on my coax shield

is their such a thing for uhf/vhf?? if so who specifically sells them

second

I have a arrow 2/440 j pole works great---- it dosn't have any radials
hanging off naturally, so since basically just the center conductor is
connected would you suspect my coax shield is 'part of the antenna'
radiating alot of stuff??

(course the shield does attach to the bottom mounting plate of the
antenna but i wasn't counting that

tnx

> straight-forward argument... and makes it circular.

Cecil's circulator is a device that gets hot when reflected
waves are present, proving that reflected waves possess
energy and power.

Cecil's TDR allows everything about a reflected pulse to
be known and measured.

Cecil's TV ghosting allows one to see the reflections with
one's own eyes.

Cecil's one foot long piece of 200 ohm feedline allows one
to observe the elimination of reflections thus proving a
200 ohm Z0-match where the one who offered the example
thought there was a 50 ohm Z0-match.

I'm a professional teacher who uses lots of visual aids.
They work well on open-minded people. But they do often
pi$$ off closed-minded people because they leave nothing
worth arguing about.

First of all, Thank you to all who responded.

I looked up the references I could and read about the antenna. I
think I learned what I need to know about it.

I was given the antenna, so I have no cost involved and no loss here.

This is what I understand about the antenna at this time.

It would appear that the antenna manufacturer markets this antenna by
way of a hyped-up techno-babble description that may not even be
accurate, and exaggerated gain. The antenna is primarily a CB design,
but the matching network allows the antenna to be tuned so that it may
have acceptable SWR on 15-10 meters but probably not on 20 meters
without a tuner. With a tuner, the antenna will function on 20-10
meters. Hams with experience with this antenna find it to be lossy
compared to a common dipole, however, it will function as a vertical
without radials at whatever desired elevation.

My plans are to play with it enough to test it and either keep it as
just something I can use without a tuner or to give it away.

More comments are welcome.

Thank you all again.

This is exactly like the ham who puts up a random length dipole,
feeds it through a 9:1 balun using 450 ohm ladder-line, and
declares that he has a Z0-match.

50 ohm
100v
source--+--1/2WL 50 ohm feedline--+--200 ohm load

Measuring the 50 ohm SWR at your source output yields 4:1.
Measuring the 200 ohm SWR at your source output yields 1:1.
It is *NOT* Z0-matched to the 50 ohms inside your source.

In a lossless system, a Z0-match to the source impedance
would imply a conjugate match and maximum power transfer.
Your example obviously does not transfer maximum power.

794. Re: Determining SWR and Transmission Line Losses ?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-10 12:45:29 UTC
From: Dave <noone@nowhere.com>
Message-ID: <A8GdnZY1Ea7uFjTfRVn-ug@crocker.com>
Source record: 75460

to determine the swr you have to figure the impedance, which can vary depending on height, exact shape, etc... no single formula, you can model with a program of course, but its likely easier to measure it.

as for losses... 100' of rg-58 on 20m has a loss of about 1.5db when matched. raise that swr to 20:1 at the load and the loss goes up to 5db (using graphs in old arrl antenna book so the exact numbers may be off a bit, but who cares). so you might lose 1 s-unit if you try to use the 40m dipole on 20m, likely something less.

now, if you use a common twin lead and drop that 1.5 db to .5db, then raise the swr to 20:1 you still lose 3db. so for all the extra problems of getting twin lead in and out of a house, and messing up the 40m match, you save 2db.

Using an omni v-pol antenna for the receiver with the problem won't help much if the 99FM xmit antenna radiates v-pol as well as h-pol -- which is typical for FM stations.

Really fixing the problem will require changing your receiver to one with better selectivity. It is being de-sensitized by that local FM station.

An option would be to install a notch filter tuned for the local FM at the input to the problem receiver. It will attenuate that local signal (and others close to it in frequency, to some extent). A "5KFM" type notch filter from Microwave Filter Company may do the job, for about $25 as I recall. Here is a link: http://www.microwavefilter.com/

Source record: 75357

The nominal impedance of a 40 m dipole, at 30 ft above an average ground, is 4700 + j0. There may be some inductive or capacitive reactance present -- depending on the exact length of the antenna -- but it will not effect the transmission line losses significantly.

100 ft of RG 58 exhibits a total line loss of about 13 dB when terminated with the above impedance. i.e. 100 W in gives 5 W radiated.

For the above analysis I used NEC 2 for the antenna model, and ARRL's TLA for the transmission line loss.

Regards,

Frank

None of those observations proves the existence of "waves of energy and power". They can all be explained more simply and easily in terms of waves of voltage and/or current (or in circulators and waveguide, waves of E-field and/or H-field).

The world is still waiting for an explanation of the detailed internal workings of *any* of those devices, done entirely in terms of "waves of energy and power". A newsgroup limited to ASCII text is not the best medium to attempt this... so will the forthcoming QEX article oblige?

Are you sure about that? Generally, a VHF TV antenna with two sets of
elements has one set for channels 2 - 6 and another for 7 - 13. FM elements
would be about 4-1/2 feet tip to tip.

NEC modeling of a 40-meter dipole at 66'

40-meters: Z= R69.5 J0 SWR (RG-58)= 1.4:1

20-meters Z= R4,198 +j1742 SWR(RG-58)= 98:1

Total Transmission line loss using RG-58

Total line loss (100 ft)= 1.278dB

Total line loss (100ft)= 11.64dB

>
>as for losses... 100' of rg-58 on 20m has a loss of about 1.5db when
>matched. raise that swr to 20:1 at the load and the loss goes up to 5db

>

Same antenna using 100 feet of 450-ohm ladder line

40-meters: Z= R69.5 J0 SWR = 6.5:1

20-meters Z= R4,198 +j1742 SWR = 11:1

40-meters total line loss=0.19dB

20-meters total line loss=0.55dB

The antenna feed point impedance calculated using EZNEC

Transmission line loss calculated using TWL

Cecil, W5DXP wrote:
"The reflection from surface "A" is canceled by an equal magnitude and opposite phase reflection from surface "B:."

Is this not analogous to what happens on a short-circuited 1/4-wave stub? The hard short reverses the phase. That, combined with travel to and from the short, produces a total phase rotation of 360-drgrees.

The result is that the open end of the short-circuited stub, the incident voltage is in-phase and of the same magnitude (no stub loss) so that no current flows between the incident and reflected sources.

It is as if one connects identical battery cells ib parallel. The impedance is, in effect, infinite between sources of identical voltage.

Optical experts must have siezed upon the opposite of this somehow. Their quarter-wave must have ben terminated in the equivalent of an open-circuit. This 1/4 wave would accept 100% of light presented at its surface, or would it need to present 377 ohms at its surface?

I am ignorant of optics and find the analogy difficult to understand.

Best regards, Richard Harrison, KB5WZI

Ian, I haven't seen you, or anyone else, offer proof that
"waves of voltage and/or current" can exist without energy.
I always thought ExH equals the power in the Poynting Vector
for any EM wave whether it be an RF wave or a light wave.

> The world is still waiting for an explanation of the detailed internal
> workings of *any* of those devices, done entirely in terms of "waves of
> energy and power". A newsgroup limited to ASCII text is not the best
> medium to attempt this... so will the forthcoming QEX article oblige?

The QEX article's present title is: "An Energy Analysis at
an Impedance Discontinuity in an RF Transmission Line".
It is mostly a review of the principles of the wave
reflection model which was invented before anyone hatched
the stupid idea that waves can exist without energy. :-)
It will be mostly old hat stuff for people who have ever
done an analysis using power reflection coefficients but
that seems to be a lost art lately.

Incidentally, a complete analysis of a Z0-matched impedance
discontinuity can be done using only an energy analysis.
If voltages and currents are actually required, their
magnitudes and phases can be calculated from the energy
components.

No net current flows but the forward current and reflected current
are constant RMS values as are the forward and reflected voltage
values. The virtual impedance at the mouth of a lossless 1/4WL
shorted stub is (Vfor+Vref)/(Ifor-Iref) where Vfor/Ifor = Z0
and Vref/Iref = Z0. Since Ifor=Iref for a lossless stub, the
impedance is zero. But the current is quite high at the shorted
end of the stub where it is Ifor+Iref.

You can estimate that current if you measure the voltage at
the mouth of the stub. 0.5*V/Z0 will yield the estimated forward
or reflected current.

The phase of reflections follows a different convention in optics.
And the index of refraction is inversely proportional to Z0. But
a 1/4WL of thin film is akin to 1/4WL of transmission line used
as a series matching section - not parallel but series. This is
essentially how non-glare glass works.

source---50 ohm coax---+---1/4WL 61 ohm coax---+---75 ohm load

50/50 = 1.00, the index of refraction for air
61/50 = 1.22, a good index of refraction for a thin-film
75/50 = 1.50, a good index of refraction for glass

> I am ignorant of optics and find the analogy difficult to understand.

I've learned more about reflections and superposition from "Optics",
by Hecht, than from any other single source. I highly recommend it.

Bob wrote:
"There`s a 99 FM xmtr a couple of miles to the SE of me, lower in elevation, right in the path of all the other stations - & right smack in the middle of the FM band."

Bob seems to be lucky that the elevation of the interferring station is enough lower that keeping the receiving antenna low hides it. That seems to be what`s going on with the car radio and the built-in antenna on his stationary radio.

Further suppression can come from a parallel-resonant trap in the middle of his FM antenna element(s). This should make the elements an open circuit at 99 MHz. Bob`s other stations aren`t on 99 MHz.

For higher Q in the parallel-resonant trap, it might be wise to use 1/4-wave short-circuit stubs. Impedance should be high for 99 Mhz and lower for other frequencies. For a folded dipole, you might try to use one, 1/4-wave short-circuit stub and locate it in the middle of the side of the dipole opposite the feedpoint. This can all be made of 300-ohm TV twinlead if desired. This may not be as effective as stubs in each side of the 1/2-wave dipole. Folded dipoles are really loops. Frequently loops have similar characteristics, open-circuit or short-circuit. Placed in the middle of each side of the driven element of the folded dipole, its resonance will be disturbed at the frequency of the 1/4-wave short-circuit stubs.

Best regards, Richard Harrison, KB5WZI

The nominal impedance of a 40 m dipole on 20 m, at 30 ft above an average ground, is
4700 + j0. There may be some inductive or capacitive reactance present -- depending on the exact length of the antenna -- but it will not effect the transmission line losses significantly.

100 ft of RG 58 exhibits a total line loss of about 13 dB when terminated with the above impedance. i.e. 100 W in gives 5 W radiated.

For the above analysis I used NEC 2 for the antenna model, and ARRL's TLA for the transmission line loss.

The results are very similar to K6MHE, but should show zero reactance on some frequency. Anyway the losses are close.

Regards,

Frank

I wish we were able to discuss this without it becoming so confrontational. As I've said to you many times, you've got 98% of this thing nailed to a tee. But that 2% is a major error from a physical standpoint. Energy is not flowing in the way you describe it. Power doesn't flow at all, but that's a different discussion. When the fields cancel, as in the anti-reflective/impedance matching scenario, energy is not conveyed in the reflected direction. There is no conservation of energy problem until you claim that that energy from cancelled waves IS moving in the reflected direction. Once you make that claim, you're forced to imagine a way for it to reverse its course, and that's where the problem lies. We've been over this a hundred times and you just refuse to accept it. It violates physics. It violates Maxwells equations. It's wrong, and I hate arguing with you about it, but as a fellow enthusiast I advise you not to print that part of your article in QEX. It's an absurdity in the midst of brilliance, not unlike myself. ;-)

For higher Q in the parallel-resonant trap, it might be wise to use 1/4-wave short-circuit stubs. Impedance should be high for 99 Mhz and lower for other frequencies. For a folded dipole, you might try to use one, 1/4-wave short-circuit stub and locate it in the middle of the side of the dipole opposite the feedpoint.

A 1/4 wave at what freq? If 99 MHz, that stub configuration will have ~ zero loss at 99 MHz, and greatest loss centered on the 2nd harmonic (not what he needs).

Me too. Please treat me the way you would like to be treated
and we will get along just fine. Oh, and thanks for the doorknob
caps. I use them now instead of stubs.

> As I've said to you many times, you've got 98% of this
> thing nailed to a tee. But that 2% is a major error from a physical
> standpoint. Energy is not flowing in the way you describe it. Power
> doesn't flow at all, but that's a different discussion.

I've been very careful to consider power as the measured energy flowing
past a point even though many others, including the IEEE, present the
Power Flow Vector right along with the current phasor. But as far as
EM wave energy and power are concerned, they are virtually
interchangeable. EM wave energy always travels at the speed of light -
imagine that. :-) The energy in an EM wave can only be stored as an
EM wave traveling at the speed of light as in a delay line. It cannot
be put into an RF battery and used as needed for an old wives' tale.
Walter Johnson recognized the close relationship between EM energy and
EM power and actually presented the "conservation of power" principle in
his book. The only difference between EM energy and EM power is time.
The joules in the joules/sec must be conserved.

> When the fields
> cancel, as in the anti-reflective/impedance matching scenario, energy is
> not conveyed in the reflected direction.

Of course, and I never said it was. That's your straw man left over from
our last argument. If the fields cancel, there is no energy available
for a rearward flow. That's why you cannot measure reflected power in
the coax on a Z0-matched system. All the reflected energy has changed
direction. But we know the internal reflected energy has traveled in
the rearward direction. What altered its momentum in that rearward
direction?

Energy must be conveyed from the far surface or the fields would not
cancel. That's called the internal reflection and its rearward flow
can be detected. Since the internal reflection wave possesses momentum
in the rearward direction, something has to reverse that momentum. We
can disagree on the mechanism that reverses the momentum of the
internal reflected wave, but the wave is there and can be detected.

The entire reason I cannot accept what you say is that you have never given a reasonable explanation of what happens to the momentum of the rearward-traveling internal reflection wave. Want to try again? Please concentrate on that one topic. Resolving the momentum in the internal reflection wave is the only way to convince me that I am wrong. I think that is the concept that convinced the QEX editors that I was right. If one accepts the conservation of momentum principle, then one has to accept a cause for the reversal of that momentum.

The internal reflection wave is illustrated in section 9.4.1 of "Optics". It has obviously traveled in the rearward direction across the width of the thin-film. What happens to its momentum and energy if it gets canceled?

> There is no conservation of
> energy problem until you claim that that energy from cancelled waves IS
> moving in the reflected direction.

Something has to reverse the momentum in the wave reflected from the far surface, i.e. the "internal reflection". If you don't know what that is, reference section 4.3 in "Optics". You have never given a reasonable explanation of what reverses the momentum of the internal reflection which, I'm sure you would agree, doesn't appear in the glare so it had to be reversed. Exactly how was it reversed?

> Once you make that claim, you're
> forced to imagine a way for it to reverse its course, and that's where
> the problem lies.

No, since it is obvious that the momentum of that internal reflection wave reverses, a reversing mechanism is necessary. I've presented a mechanism and you haven't.

> We've been over this a hundred times and you just
> refuse to accept it.

Yes, and you refuse to accept it. Momentum doesn't change by magic. There has to be a physical reason. I have presented my take on that physical reason. You have presented no explanation. Between having an explanation and having none, guess what my choice will be?

Please just explain how the momentum in the internal reflection wave gets reversed within the boundary conditions of the classical wave reflection model. No quantum physics, please.

So let's concentrate on that narrow topic of what happens to the momentum in the internal reflection wave, shall we? Here's a diagram where 'n' is the index of refraction and the internal reflection from surface 'B' is shown:

```
| |
laser--------air----|----thin-film-------|----glass---------
n-1.0 | n=1.2222 | n=1.4938
A <--reflection----B
```

The internal reflection that I have been talking about occurs when
the forward wave in the thin-film encounters surface 'B'. The
reflectance is 0.01 at that surface so one percent of the forward
irradiance will be reflected. It will have momentum in the rearward
direction. Please tell us what alters the momentum of that reflection
such that it doesn't appear as glare at surface 'A' and instead
reverses direction and joins the forward wave.

To Jim, and anyone else who wants to discuss it. I've created
a graphic illustrating reflections from a thin-film when the
incident laser beam is at an angle to the thin-film surface.

http://www.qsl.net/w5dxp/weblaser.GIF

Question for Jim: I can see Reflection A and Reflection B.
I can measure the irradiance of Reflection A and Reflection B.
Are the two reflections really there or not? If they are there,
do they possess energy and momentum?

That will get us started.

Having trouble responding to the above posting. Hope it is not duplicating what I have tried to send before.

The nominal impedance of a 40 m dipole on 20 m, at 30 ft above an average ground, is
4700 + j0. There may be some inductive or capacitive reactance present -- depending on the exact length of the antenna -- but it will not effect the transmission line losses significantly.

100 ft of RG 58 exhibits a total line loss of about 13 dB when terminated with the above impedance. i.e. 100 W in gives 5 W radiated.

For the above analysis I used NEC 2 for the antenna model, and ARRL's TLA for the transmission line loss.

The results are very similar to K6MHE, but should show zero reactance on some frequency. Anyway the losses are close.

Regards,

Frank

It doesn't show up on my web browser. Do you have the URL right?

If you have a photon zinging through space it posseses both energy and momentum, and they are each an easy function of the wavelength.

To pick nits, if you have a _stream_ of photons zinging by it will posess, on average, power and thrust (or whatever the time-derivative of momentum is called). If reflections A and B are both there they will each carry a certain amount of power and exert a certain thrust somewhere.

If you have actually set up this thin film experiment and measured two seperate reflections then they are indeed there. You can debate whether the reflections are truely reflective of the theory that you're trying to demonstrate or if they reflect (or perhaps reflect off of?) imperfections in your experimental setup.

While 1/4WL (or 3/4WL or 5/4WL) of 450 ohm ladder-line yields an
impedance at the transmitter of 43 ohms for a 50 ohm SWR of 1.16:1
without a tuner and very low line losses. What could be sweeter?

Before I married my wife (40 years ago in August!) I showed her the ham shack and had a QSO on 160m (AM phone in those days!) with her present. I let her say hello to some guy across town, warning her that it was illegal in the UK then for someone unlicensed to speak over amateur radio so she'd better make it quick. Her first words on 160m were, " I think I'm breaking the law by talking to you...." !!! Thank God it wasn't 20 metres or the whole world would have heard her!

She's been very tolerant ever since...

OK, now I can see your post. Yes, those reflections are real, and the
numbers are probably about as good as you'll get from clean AR coated
glass, IFAIK (_dirty_ AR coated glass will give you much larger
reflections). Laser rangefinders get one heck of a return when they
fire, and are limited in the minimum range that they can measure because
of the time that it takes for the receiver to recover (or be turned on,
depending on the LRF architecture).

I'm confused by your confusion -- what are you trying to do, and why do
you have to ask?

Dang, you guys are fast. You must have caught it just as I was
downloading the simpler version. Please try again.

> If you have actually set up this thin film experiment and measured two
> seperate reflections then they are indeed there.

I probably could set up that experiment but right now I'm just
talking about it. I'm sure the angle of incidence could be
adjusted until both reflections show up as separate dots on the
retina. How much laser power will burn a retina?

In any case, essentially the same diagram is in any good physics
book. Page 1350 in "Sears and Zemansky's University Physics" by
Young & Freedman, Texas A&M custom edition. Page 505 in "Elements
of Physics" 2nd edition, by Shortley and Williams (c) 1955 :-).

I'm not confused. I'm trying to alleviate Jim's confusion. :-)
The next step is to slowly collimate the beam normal to
the thin-film and watch what happens to the reflections. Jim
implies there won't be an internal reflection from surface 'B'
when the beam is collimated. I say it will still be there
possessing energy and momentum. That's the crux of our argument.

The laugh-athon continues Roy's "I don't know's on third!" math.

Even with all precision removed (two places is two places too many :-)
the rays show absolutely no evidence of refraction (which makes the
reflections bogus), and the angles are unmarked (which makes the 10mW
labels spurious), and the term irradiance was pulled out of a hat (it
is radiant flux - iff we are to believe anything).

Back to Optical kindergarten.

Funny that Eugene Hecht, of "Optics" fame, disagrees
with you. "When we talk about the 'amount' of light
illuminating a surface, we are referring to something
called the irradiance, denoted by I - the average energy
per unit area per unit time."

All of Hecht's interference equations are presented
using 'irradiance' not 'radiant flux'. I quote those
equations in my article and possibly in this thread.
That's why I am using 'irradiance'.

This seems a bit academic. I don't know anyone goofy enough to
run 100 feet of RG-58 with 100:1 SWR; do you?

> While 1/4WL (or 3/4WL or 5/4WL) of 450 ohm ladder-line yields an
> impedance at the transmitter of 43 ohms for a 50 ohm SWR of 1.16:1
> without a tuner and very low line losses. What could be sweeter?

What could be sweeter? I'd say a 20m dipole, coax fed. (Mine shows
1.0 SWR at band center, and under 1.5 full-band. Not fussy about feedline
length. Feedline also runs through a metal conduit, with no problems.
No tuner of ANY kind needed, distributed or conventional. Minimal
loss. QRO FB.)

But if one MUST operate a doublet far from 1/2-wave resonance, then
a balanced feedline plus tuner is the way to go. And implementing the
tuner in distributed form by tuning feedline length has some advantages
over a conventional, lumped-constant tuner. To my mind, the MAIN
advantage of the tunable feedline is that it can handle high power at
low cost. I'm a bit surprised you don't talk that advantage up more.

Well, a 66 ft. dipole used on 20m does exhibit gain over a
33 ft. dipole used on 20m by almost 2 dB.

I suspect that your home FM radio is very insensitive. Car radios are usually very good since you drivee through all the worst-signal places. Your home radio is either a poor design or is sick. Sit it on top of your car and put a 19-inch wire on the "hot" antenna terminal. It should receive about as many stations as the car radio. If it doesn't, get a new home radio - it would likely cost too much to fix what you have even if you could find someone who thought they knew how to do it.

I wouldn't worry about antennas until the above test showed that the radio works well.

I have had some experience with rooftop antennas when I lived in Troy, NY. During the early 1970's there were not too many local FM broadcast stations in the area. When I put up the antenna, I was receiving signals on a regular basis up to 125 miles, and sporadically up to 200 miles. As the number of local stations increased, my ability to receive distant signals decreased. This was both from the fewer number of channels unoccupied by local stations, and the tendency of strong signals to desensitize my receiver. I used a rather lengthy Channel Master Yagi FM antenna, which I don't think is still on the market.

Perhaps you are in an area with strong local FM signals. You should try to drive around and see where you can pick up distant signals from your car. As an example, the Poughkeepsie / Kingston, NY metropolitarian area has only one or two UHF TV stations, but many local FM radio stations. Most residents rely on cable TV for stations from New York City or Albany, NY.

That's the perfect answer, but you may be able to achieve satisfactory
results by - surprisingly - adding an attenuator (a 6db 300-ohm pad
made from resistors would be a good start) in line with the antenna
lead. RF overload characteristics are proportional to the square of
the incoming signal, so the interference will be reduced more than the
desired signals. Also, a three-element FM antenna won't be nearly as
selective as a larger yagi of the type shown here:

http://www.starkelectronic.com/fm.htm

Putting one of these on a rotator will normally run rings around any
cable company unless you have interference from the new IBOC digital
radio signals.

>
==========

Just out of curiosity I calculated the following details of 100 feet
of RG-58 terminated with 4700 ohms at 14 MHz.

Line input impedance = 12.3 - j37.7 ohms.
SWR vs 50 ohms at termination = 88.6
SWR vs 50 ohms at generator end = 6.35
Matched loss of 100 feet of line = 1.3 dB
Actual loss = 11.4 dB
With 100 watts input, output into 4700 ohms = 7.2 watts.

A tuner is essential. There will be additional loss.

By the way, at the first current loop, line current is 3.41 amps. As the inner conductor diameter of RG-58 is only 0.78 mm, the temperature of the pvc jacket can rise to about 20 degrees C above ambient. So don't hold the line in the hand for too long.

Reg.

> . . .

Most people can't or don't rotate a 66 foot dipole, and it has that much gain over a dipole half the length only in two specific directions. It has a gain of one dB or more over the shorter dipole only over 60 of the 360 degrees of the compass; and for 280 out of 360 degrees, it has *less* gain than the shorter dipole -- in fact as much as 14 dB less. For most people the longer dipole is a poor choice unless there's a specific narrow direction you want to favor at the expense of most other directions.

You lose a lot of information when you reduce an antenna pattern to a single "gain" number, just as you do in reducing complex data to an average. Keep in mind the statistician who drowned while crossing a creek whose average depth was only three feet.

Hi all....
I am thinking of making an 80 meter delta loop, fed at the top with coax
with a matching network at the bottom for 80 thru 10 meters.
Am wondering if this is feasable....any ideas?

845. Interesting Cloud Burner Antenna

Newsgroup: rec.radio.amateur.antenna

http://www.hamuniverse.com/supernvis.html

The claim is that a dipole 7 feet off the ground has
a 10db gain over a G5RV at 50 feet.

Is that possible, or hype?

846. model/dipole help

Hi
'
Ihave sgc 237 going into about 5ft of ladder line (mounted at base of mast) to a horiz ctr feed dipole
'
it measures about 20ft 7" rf 'hot' side and 33' 7" rf gnd side

I am only haveing a mac, and never used any modeling software, can someone help me out, and given the above data what are the

assumptions or pro's /cons' that would be expected at these dimensions? (aside from the obv being it's kinda short)

The tuner will tune it all bands 6m to 160m my max swr is 1.5 and usually is 1.2

my goal is to learn all about where i am /or not resonant , giving harmonice or volt/vs currents etc (or perhaps that dosn't apply w/a antenna mounted tuner)

Seems i also give a bit of tvi on 20m broadcast and a bit on 80m to the direct tv

might just be rf overload however i'd like in general to learn about my antenna and what the numbers mean

any help is greatly appreciated, perhaps i can use that info if my antenna is at a really odd/bad length i could tweek it to make it better

thou i don't have much space left

thanks

> The term "accept power" is interesting. To me, it's just a measure
> of the input impedance of the antenna. If the resistance (radiation
> plus loss resistance) is zero, you're not going to get it to absorb
> power no matter what you do.

Yes. And the input conditions depend on the ability of the radiator to generate EM fields. No current can enter and "flow through" a radiator if it doesn't have some place to go. If a radiator is not electrically long enough to allow differential current to exist along its length, it cannot generate EM fields. It is the di/dt along the radiator length that generates those fields.

Adding a matching network at the antenna input doesn't change the instrinsic ability of an antenna to radiate. That is determined by the factors described in the paragraph above. A matching network can permit the tx to increase its rated, safe output power while driving that poor antenna, but any extra power available at the antenna input because of that will be subject to the same poor radiation efficiency as if the matcher wasn't used. And much of any added power from the tx may get dissipated in lossy output system components other than the antenna, rather than being radiated. The antenna itself will still have the same directivity/gain that it had before the matching network was added.

Improving the ability of a poor antenna to generate EM fields per unit of source power is possible in a limited way only by increasing its electrical length. "Capacity hats" and inductances incorporated into the radiating structure can be used, as examples. This also raises the antenna radiation resistance and reduces the reactance at the antenna input -- making it easier to match into, and reducing system losses.

It's could be true for 30m or 10m. Certainly not true
for the bands for which the G5RV was originally
intended namely 80m, 40m, and 20m. 12m comes as a
bonus.

You can make a G5RV just about as good as a dipole
on all HF bands.
0'-16' 20'
xmtr---coax---+---LLLS---+---450 ohm LL---+-102' dipole

The key is the LLLS, ladder-line length selector that
allows selection of 0'-16' in increments of one foot.
It requires four 4PDT relays, like the Omron LY4.
The relays are controlled from the operating position
but auto-switching would be easy to implement with a
directional coupler and a couple of op-amps. The
largest loop of ladder-line is only 2.5' in diameter.

You have reasonable feedpoint impedances for 30m-10m
that the tuner should be able to match. Below 8.6 MHz,
the mismatch starts to climb. It's not bad on 40m but
very bad on 80m. So you have a reasonable setup for
40m-10m, pretty poor for 80m.

Anecdotal evidence. First note he says 160 meter G5RV, one could assume he has doubled the size to 204 feet to meet this claim. Run a 204 foot dipole through EZNEC on 40 and you can see why the claims may be valid in some directions.

The feedline has a certain efficiency. A matching network at the antenna
has a certain efficiency. If the matching network at the antenna is much
more efficient than the feedline, then it may be a reasonable solution.
An SGC-230 tuner mounted at the base of a 22 foot vertical makes a
reasonable antenna for 40m-10m operation. Feeding that same antenna
through coax from an SGC-230 in the shack makes for a pretty poor
antenna on most bands except 30m. Same antenna, same tuner, different
configuration = wildly different results.

> The
> antenna itself will still have the same directivity/gain that it had before
> the matching network was added.

Yes, but the SGC-230 at the base of the antenna may be operating at
50% efficiency while, if you moved the tuner back to the shack, the
feedline might be operating at 10% efficiency. The choice is clear
(if there are no thieves around. :-)

I didn't look at it but just noticed 'nvis' in the title.
Of course, a dipole at 7 feet will have near-vertical gain
over a G5RV at 50 feet. Near-vertical gain is NOT what the
majority of hams desire. Near-vertical gain is the antithesis
of DX.

In the typical J-pole antenna, the shield connects to the long element
and the center to the stub. I don't know your antenna in particular,
but I would suspect this is the case and don't believe it is considered
a radiating element.

Actually, you can charge up anything to produce a field. If the field is
static, though, it won't radiate. Also, short radiators work just fine
if you excite them with frequencies whose wavelengths are on the same
order of magnitude. Finally, if you can keep the losses down, radiators
that are small compared to a wavelength of the frequency you want to
radiate, work well, too, though you may have to be satisfied
with narrow bandwidths and make heroic efforts to feed them. Finally,
you might be more accurate if you substituted 'dq/dt' with 'di/dt',
but even that won't guarantee radiation: transmission lines have
plenty of charge acceleration, but are designed specifically to
not radiate. You might want to rethink your ideas. Try not to
be so reductionist. You don't want to end up like Cecil.

We think we know that the impedance at the center of a thin wire antenna in free space is something on the order of 70 ohms at resonance (quarter-wave ears with the end fringing factor thrown in).

We think we know that the VSWR bandwidth increases as that thick wire becomes fat. We think we know that the end fringing factor goes up as the antenna gets fatter.

What I'm suspecting the further I look into it is that the NEGATIVE image of that dipole antenna (a slot cut into an infinite sheet of conductor fed at the center across the slot) is also resonant, but the impedance is going to be something on the order of 350 ohms. Jasik shows a method of off-center feeding that reduces the impedance to something on the order of 100 ohms.

What is NOT mentioned is the aforementioned VSWR "goodness factor" going up with a fatter (wider?) slot.

Is there a better reference to slot antennas than Jasik?

Jim

Israeli couple working for Mossad subvert global computer fire walls
....

ZNET

MICHAEL HAEPHRATI --- ENEMY OF THE STATES OF THE UNION

NO. # ENEMY OF THE U.S.A -- Michael Haephrati -- [not Lawrence Franklin, who pee'd in the face of the Pentagon and got away laughing, but Michael Haephrati, 41, who had undergone a bitter divorce from Raziel Jackont's daughter eight years earlier -- and who, according to Jackont, was the model for a shady character in the novel, and who is at the heart of darkness of this espionage case against all main U.S. computer companies].

Interpol and FBI and Mossad investigators now admit that Haephrati was involved in a much larger criminal conspiracy.

In a statement released over the weekend, police said they had discovered a Trojan horse on Jackont's computer that they were able to trace to an unnamed source. The Trojan allowed the person to control the computer, make changes to its programs, monitor everything it contained and raid it for information -- all without leaving any hint of the Trojan's existence. Investigators also discovered that the same person had sold the software to three of Israel's largest private investigation companies, which allegedly used it to illegally collect data for their corporate clients and undermine US money transfers and military security.

Hundreds of companies -- including many U.S. and European firms -- have been spied upon without realizing it.

Last week's arrests included an executive of a major satellite television company, suspected of spying on a cable television rival, and officials of two cell phone companies, suspected of eavesdropping on a mutual rival. Also accused in the scheme was the Israeli importer of Volvos and Hondas, suspected of spying on the company that imports Audis and Volkswagens.

The first of several police statements did not name the alleged author of the scheme but said two Israelis had been arrested in London for allegedly manufacturing and distributing the Trojan. Scotland Yard confirmed that Haephrati and his wife, Ruth Brier-Haephrati, 28, were being held for extradition to Israel for "unauthorized modification of the contents of a computer," according to the Associated Press. They have made no public comment on the charge.

Security experts say they've discovered a Trojan horse that records e-banking user details and Web surfing habits.

Antivirus company Sophos is warning that the Banker-AJ Trojan is targeting online customers of British banks such as Abbey, Barclays, Egg, HSBC, Lloyds TSB, Nationwide and NatWest. The Trojan affects computers running Microsoft Windows.

The company said that once installed, the Trojan waits for users to visit their online banking Web sites, then captures passwords and takes screenshots of the session. The information is relayed to the hackers behind the ploy, who use the data to steal money and highly classified corporate and military information.

Last week, police arrested 16 people in Israel, including senior executives of some of the country's leading high-tech companies and the private investigators they had allegedly employed. At the same time, British authorities, acting on an Israeli request, arrested the former son-in-law and his wife in London and are holding them pending an extradition hearing this week.

Israeli newspapers, which had been alerted to the case last week but were prohibited from publishing details until the roundup was completed over the weekend, characterized it as the biggest case of industrial espionage in the country's history. "No one remembers a case like this in Israel -- an affair with such scope of investigation involving technology at this high level," said Chief Superintendent Rafi Levy, spokesman for the national police force.

"It's the next generation of phishing attacks," said Graham Cluley, senior technology consultant for Sophos. "These rely on people going to real, legitimate sites. Once the Trojan determines that you've gone there, it starts taking keystroke logs and snaps shots of machines and sends it back to hackers."

Phishing scammers typically set up bogus Web sites to capture victims' personal information. They send e-mails that appear to come from trusted companies to lure people to the fake sites, where victims are asked to enter information such as credit card data. Attacks frequently target bank customers, but eBay and Amazon.com have also been recent targets.

Previous Next Barclays Bank said it had seen the technique of using legitimate sites before. A representative for the company said, "This type of Trojan is something (we) have been aware of for some time. We are working with (the) industry to identify the next steps to help combat fraud and are interested in educating customers."

Sophos also said it had seen a similar Trojan, Tofger, a few months ago, but the technique had mainly been used in Brazil.

"We did see another one a few months ago," Cluley added. "Some of the Brazilian ones just wait for the user to look at a Web site with the word 'bank' in (it), but this one specifically targets many well-known

U.K. banks, and that makes it notable."

Gentlemen,

I work for a student transportation company using UHF radio communications. While I have played around with CB radios several years ago I have no experience with UHF.

Our system operates on either of 2 channels near 470MHz. Channel 1 transmits via a repeater located in the hills a few miles away, while channel 2 is direct.

For most of the last school year we have operated on channel 2 as channel 1 wasn't working. A company recently came out (not following known company authorization proceedures), and apparently repaired a faulty repeater. Our company was charged about $185.00 for parts and over $600.00 for labor. The rate worked out to be $80.00 per hour over 7.5 hours. Not only does this seem a wee bit steep to me, but the communications are still poor on channel 1.

Assuming that the repeater is fine now, the problem seems to be more related to the individual busses. Over the course of time our mechanics have swapped-out radios, mics, and probably antennas as well. Given the nature of the problems and my previous (limited) experience with CB, my suspicion is that the antennas on the busses need to be tuned.

I used to tune my CB antennas with an SWR meter and get good results. I understand the basics enough to be able to do that and could probably teach our mechanic as well. However, since I have no experience with UHF I don't know if there's more to it with UHF over standard CB and if there is more equipment required than an SWR meter. I am just having a real difficult time paying $80.00 an hour for someone to do something I used to do quite easily.

Mike

"Antennas" by John Kraus, second edition, McGraw Hill, 1988, (ISBN
0-07-100482-03) has a chapter on slot and similar antennas. It says the
impedance is about 500 Ohms, and so to feed with 50 Ohm coax you need to
feed well off centre (it suggests about lambda/20). If the slot is
vertical, the polarisation is horizontal. There are some journel
references.

"HAARETZ WORLD JEWISH NEWS" CONFIRMS SUSPICIONS THAT CLASSIFIED DATA
SPY HAEPHRATI [TROJAN HORSE COOKIE/VIRUS/BUG] WORKED FOR MOSSAD.

When will the U.S. criminally charge AIPAC and Lawrence Franklin???

direct from Haaretz:

"Haephrati, 41, who studied computers, is described by relatives as
being unable to hold down a job. Once, while unemployed, he allegedly
told relatives he was working undercover for the Israeli security
forces."

"HAARETZ WORLD JEWISH NEWS" CONFIRMS SUSPICIONS THAT CLASSIFIED DATA
SPY HAEPHRATI [TROJAN HORSE COOKIE/VIRUS/BUG] WORKED FOR MOSSAD.

When will the U.S. criminally charge AIPAC and Lawrence Franklin???

direct from Haaretz:

"Haephrati, 41, who studied computers, is described by relatives as
being unable to hold down a job. Once, while unemployed, he allegedly
told relatives he was working undercover for the Israeli security
forces."

$80 per hour isn't a bad price if the work is good. UHF requires more expensive instruments than CB, they amortize that in the labor costs -- in other words that $80 per hour is for the guy _plus_ the equipment.

Assuming the radios in the busses are in good shape (you could send them out for servicing and alighnment/checking for much less than you could have the guy come out and do it) you are left with antennas and cabling. I wouldn't expect that it's _just_ the antennas - coax can be pretty lossy at those frequencies, if it's been beaten up it'll show.

So get an SWR meter that'll work reliably at 470MHz, and try adjusting some antennas. Try replacing coax as well, and if either fix seems to work then keep it up.

thank you very much Cecil. I guess thats all do to the small size
(antenna :)))

i really need to add some length to improve 80m and 160 i can do it
but not in a straight line,

at the end i'd hve to make a turn and go down the other side of roof
guess i'td end up sorta looking like a big fat square U shape thingy

greatful for the help

QUESTION:

if i swapped the hot w/the rf gnd effectively making >>>
33.7hot 20f.7 gnd would that be better??

i make the gnd longer as it said to in the sgc manual

thanks again

What does "poor" mean?

>Assuming that the repeater is fine now, the problem seems to be more

This needs more description. If just ONE bus operates fine, then you
don't have a problem with the repeater.

>Over the course of time our mechanics

Commercial mobile is usually quite bullet-proof and is far more
tolerant through over powered gear. The antennas would have to be
seriously whacko, like twice/half their usual size. In other words,
visual inspection with a ruler and basic understanding of wavelength
is enough (a whip roughly 16cm tall).

Hi Mike,

Sounds cheap at $80/hr. Frequently service problems are reducible to
connections. In your case this would be transmission line
connections, connectors, and antenna base clamping (screws or nuts).
Again, all of this is easily determined through visual inspection and
a pocket full of screwdrivers and pliers.

Hi Myles,

No such thing as hot/gnd as you use it. This is not household power wiring. You can swap the connections, but this will accomplish little. That is, unless you have failed to choke SGC wiring; then although everything will be repeatable (even with new symptoms), why it gives odd operation will be a mystery. (The solution to the mystery will be choke all SGC wiring.)

I differ on that opinion. My 40M/80M operational preferences are definitely for close-in communications, such as getting on the Noon-Time net, various in-state 75M nets, and other "local" activities". The lower noise factor of the NVIS antenna helps, too. Of course, its best to have two antennas, one such as NVIS and another well placed dipole, for optimum choice.

Mike,

Without knowing you, I have to only guess at your previous "CB" experience, and in doing so, will guess that it is a far cry from the knowledge and experience a good LMR technician has. Commercial radio is not CB! Only guessing from the description of your system that you gave, that is is poorly maintained, at best, and that the repeater had probably been neglected for quite some time? Several hours of labor would not be prohibitive, under those circumstances.

Assuming you can properly solder/crimp, and install RF connectors, I'd guess that you probably can save some money by doing some of the more basic work yourself. However, you will need more than a CB type SWR meter. I'd suggest a Bird Model 43 with the appropriate slug for your frequency and power. That will set you back at least $300.00+. Also, you probably ought to purchase some good quality connectors, antennas, and antenna cable/NMO installation kits as I expect you will find several of the busses needing them.

Good luck trying to do it yourself.

Ed K7AAT

Modeing shows that radiating current can occur on a J-Pole feedline due to mutual coupling from the antenna. The amount depends heavily on the length and orientation of the feedline. The main effect of the current on the pattern is to distort the main lobe, reducing the amount of signal directed horizontally. I suspect that the widely varying reports on the effectiveness of a J-Pole are due, in part, at least, to different feedline lengths and orientations and therefore different amounts of feedline radiation.

If there is significant current on the feedline, it might take a couple of current (choke) baluns, placed about a quarter wave apart, to reduce it to a small value.

Most people don't realize that ground plane antennas are subject to the same phenomenon.

Lo and Lee give the simple relationship between an antenna and its "negative" (e.g., slot vs dipole made from flat material the width of the slot) on p. 2-15 of their _Antenna Handbook_: Zslot * Zstrip = 1/4 * Z^2 where Z = the intrinsic wave impedance of the unbounded medium where both antennas are situated (e.g., free space).

What are you disagreeing with? How much DX do you work with
your NVIS antenna? Do you really think the majority of hams
are only interested in local communications on HF?

I guess my disagreement was with the word "majority"... but then, I was
thinking of 75M/40M and not the higher bands. I would say on the two bands
I meant to restrict my comments too, that more hams probably do communicate
"locally" rather than hunt DX.

Mike, what is your specific title or role within this company? are you a
driver? director/manager of operations?

"Playing around with CB radios" experience should not be referenced for this
situation - while interesting - no directly relevant. You are discussing a
land-mobile system that was likely designed and installed by a professional
company in your area. For example, FCC documents had to be filed for this
repeater, frequencies coordinated and applies for and appropriate licenses
applied for.
I am assuming that you are NOT using the General Mobile Radio Service (GMRS)
solution.

The "radio system" you described for your student transportation company is
a "dual purpose" design. Channel 1 provides distance communications via an
operational repeater, when communications via Channel 2 would not be
possible (terrain, distance, etc.). Channel 2 also provides communications
channel between your buses (special event, etc.) when they may be out of
range of your local repeater.

> For most of the last school year we have operated on channel 2 -- as
> channel 1
> wasn't working.

So, you did not have an operational communications system (Channel 1) for a
period of time? And this did not cause problems in your day to day
operations?

> A company recently came out (not following known company authorization
> procedures), and apparently repaired a faulty repeater.

It is UNUSUAL for an operational repeater (with this type of service) not to
have a contract or service agreement. Who owns this repeater? Your
transportation company? Your company's legal advisor should be consulted
about agreements and terms.

> Our company was charged about $185.00 for parts and over $600.00 for
> labor.
> The rate worked out to be $80.00 per hour over 7.5 hours.
> Not only does this seem a wee bit steep to me, but the communications
> are still poor on channel 1.

We can only assume that this work was for work on a repeater that you own -- and was not covered under a maintenance agreement (known in the trade as "break-fix" coverage).

I do not know "where you are" to comment specifically about regional differences in US labor rates, HOWEVER - the labor charges you are quoting are appropriate (almost identical to my Honda dealer - BTW).

You are making 2 mistakes here (common with entry level managers)

Confusing an "hourly labor charge" with a personnel hourly rate wage -- which is incorrect. The "hourly labor charge" usually includes the overhead for the company, transportation to site, the laborer's benefits, etc. If you are an operational manager - your financial officer or director will know this difference.

The other is that you assume that productivity is constant for all employees --
that's not true -- and you can look your bus shop floor and quicky identify workers that perform higher qualtiy in less time than other workers - are you paying them more?

You stated that you did not have an operational repeater (channel 1) for almost all last school year. So how are you determining communications are "still poor on channel 1" ??

> Assuming that the repeater is fine now, the problem seems to be more
> related to the individual busses.

This is a contradiction - you paid for repairs - is the repeater working satisfactory or not? Or are you now telling us the real problem?

> Over the course of time our mechanics have swapped-out radios, mics, and
> probably antennas as well. Given the nature of the problems and my
> previous
> (limited) experience with CB, my suspicion is that the antennas on the
> busses
> need to be tuned.

I signal losses with coax at UHF (470 MHz) are far greater than at 27 MHz (CB).

I have no idea who installed your first radios in these buses -- IF your company did it themselves -- without basic equipment to "cut" these UHF antennas -- then this is part of your problem.

Mike - you have a "broken" operational process here -- that needs to be addressed - the company that fixed your repeater likely has a group of installers (who install the radios for public service in your area - police,

fire, ambulance, etc.) that deal with this every day and can correctly advise you (and help you set up the correct process) for repeatable and reliable results.

> I used to tune my CB antennas with an SWR meter and get good results. I
> understand the basics enough to be able to do that and could probably
> teach our mechanic as well. However, since I have no experience with
> UHF I don't know if there's more to it with UHF over standard CB and if
> there is more equipment required than an SWR meter.

Now, you are starting to describes "changes in your operational processes" that need correction. First, I assume that you are responsible for this area of the company?

You should identify 1 or 2 individuals within your company to "handle" the radios and antenna installations and changes on these buses. You can likely find someone -- instead of mechanics -- who should be working on the buses. These individuals can be trained to correctly handle this work -- and to assure proper operation.

Purchasing the proper equipment (SWR meter) -- this really depends upon:

The number of bus radio systems you are maintaining;
Your "bus replacement cycle" each year (new buses replacing old buses)

IF you wish to internalize this function - site down and have a meeting with your local company -- they can properly advise you to the proper equipment you should buy and properly educate your staff to use this equipment.
As an alternative, you can ask for a price for such services from this company (on a "per bus" or "guaranteed number")

> I am just having a real difficult time paying $80.00 an hour for someone
> to do
> something I used to do quite easily.

Mike, to professionals in the radio communications field - this statement can be - very insulting -
"I pay a professional mechanic to do work on my car at $75 to $80 hour - which I probably could do -- BUT NOT at their productivity level (I do not do this work everyday) -- YET you are telling me that you won't pay $75 to $80 hour for a professional radio tech or engineer to work on your repeater -- that you have no training to troubleshoot or repair."

IF you truly believe this - KEEP IT TO YOURSELF.

Mike, you may ask - what in the h^%^% do I know about transportation, bus systems or telecommunication systems?

I worked for Greyhound Lines as the first Information Center Manager (for the then new PCs, LANs and national network) in the early 1980s. In that position I worked with over 63 bus maintenance and repair centers nationwide as well as 2 major rebuilding operations.

Today, I serve as global practice leader for network and telecommunications at an international consulting firm.

I am not going to send you "an invoice" for the advice above - my business is operational excellence, cost effectiveness and outstanding quality.
Work on those 3 principals.

gb

"Antennas" by Krause and Marhefka (ISBN 0-07-232103-2) has a useful
section on slot antennas, They suggest an off-center feedpoint of
lamda/20 will provide 50 Ohms. They don't specifically cover your VSWR
question, but a couple of trials will provide an easy answer.

I have gotten to where I don't even worry about the loss of a well constructed choking--balun/unun in the circuit--better to be safe than sorry...

If the decoupling is designed into the antenna, using cones, bells, sleeves, etc, there is little if any loss. Being as the feed radiation skews the pattern up off the horizon, adding decoupling usually ends up with a "gain" at that low angle. Also, I've heard different types of "J" feed methods, naturally decouple better than others..This also applies to the ringo's, etc. The gamma loop matching device on a ringo does a halfway job of decoupling the line, but it can always be improved by a 2nd decoupling section. I don't use conventional ferrite chokes when decoupling VHF/UHF antennas. IE: If I were to add additional decoupling to a ground plane, I would use a 2nd set of radials, or a sleeve, vs a ferrite choke. MK

Which I calculate to be 266 ohms. However, a couple of other references to Kraus give the answer as more like 500 ohms, so now I'm the guy with two watches who is never sure of what the time is.

yes, i want to match it to a 50ohm amplifier,why do you think it should be 37ohm, i have simulated it using EZNEC and the source impedance is 1.684 - J 4592, is there something wrong in that? it is 1/8 wavelength monopole.

Well, undoubtedly...

the 1.684 is the "pure resistance value", and this would best be at 50
ohms...

if "- J 4592" is a real minus 4592 ohms cap reactance--it would be good
to insert a +Jx of 4592 ohms (an equal and opposite inductive
reactance)... so that Jx ends up zero...

... at that time you will find the finals in the amp start lasting
indefinitely--and you will not be bothered replacing them every few
minutes or so...

Warmest regards,
John

Try a loading coil in the center of the 1/8 wavelength.

Thanks, Tim. I am familiar with such issues, although I've had no reference points for this type of work. If that is the prevailing rate for UHF work then I'll accept that.

>
> Assuming the radios in the busses are in good shape (you could send them

That's where I was headed with this. I have no desire to replace qualified service companies or personel, rather, it seems worthwhile to look into the feasibility of moving some of the more routine service requirements in-house. If it's not practical for us to tackle the antenna tuning/coax/connections ourselves, then we'll just have to deal with that.

>
> So get an SWR meter that'll work reliably at 470MHz, and try adjusting

Thanks. I was concerned about there being some differences in the process that I was unaware of between CB and UHF. My limited understanding of antennas leads me to think that the principals remain the same and therefore the process should as well. Nevertheless, it seemed appropriate to ask.

Hi OM,

Your problems with modeling go much further. The impedance you reported was seriously low, even for an 1/8th wave. What others were trying to communicate to you is that even the best 1/4th wave (a standard sized whip or monopole) will only give you 35 to 37 Ohms, not 50 Ohms. However, this is rarely an issue in achieving good performance. A 1 Ohm antenna, on the other hand, seriously begs close examination, patience, and care in feeding.

I used an antenna quite similar to this (mine had only one ground reflector)
for local (within 300 miles) 40 meter ssb. Mine was at about 16' high.
About 1/8 wl on 40. It was consistently 2-3 s units better than the the high
(70') 40 meter dipole when working stations within about 300 miles. 300-1000
miles they were very close. For DX the high dipole was always better.

Here's a good web site that explains the phenomema

yes, a wire in free space has a velocity factor... if the formula for the antenna in question does not all ready take that velocity factor into consideration, you will need to consider the velocity...

... there is also "end effect"...

... simplest thing to do would be to use the formula which takes this all into consideration...

... first, I would google for "shortened antennas" or "shortened radiators" and get a bit more familiar with "loading" the antenna to resonance...

Actually, the $300.00 will barely get you the wattmeter at a reputable communications product dealer such as Tessco. I believe the individual elements would run around $65.00. You can see Tessco's listing at:

http://www.tessco.com/products/getProductInfo.do?sku=43948

More information on the Bird model I cited can be found at:

http://www.bird-electronic.com/products/product.aspx?id=81

There are other units that would work well, too, such as the Telewave model 44 watt meter. That one costs around $390.00 but doesn't need separate elements.

Again, a reminder, these are professional tools and you still need to know how and what to do when you find an antenna problem, and what proper parts to obtain.

The principal is the same, but remember you are dealing with frequencies about 20 times higher so what you are use to will be multiplyed by 20. That is if you were cutting off an inch at a time theh you only need to cut off about 1/8 of an inch. Also make sure the SWR meter will work at the higher frequency. One desinged for a higher frequency will work at a lower frequency just fine if you can generate enough power for the pickup. One for a lower frequency will not work on a higher frequency as the pickup will start approaching a large portion of a wavelength. Also with lossey coax (which most all are at 400 mhz, the swr will be masked so a 3:1 or so at the antenna will show up as almost a perfect match at the transmitter end.

> Yes. And the input conditions depend on the ability of the radiator to
> generate EM fields.

"Ability" could be a misleading term. If 100 watts is fed to a very short dipole, it will generate just as big a total field as a half wave dipole fed 100 watts (neglecting conductor loss). So for a given power input, it's just as able to generate an EM field as the longer dipole. It does require a lot more current. You might consider that to mean it's less "able" to generate a field, but if so, I think you should elaborate in order to avoid perpetuating misconceptions.

> No current can enter and "flow through" a radiator if
> it doesn't have some place to go.

I'm not sure what that means. A radiator is a circuit. Any current which flows in one terminal must flow out the other. That's true for any antenna of any kind.

> If a radiator is not electrically long
> enough to allow differential current to exist along its length, it cannot
> generate EM fields.

There is no such radiator. There's no threshold below which current
can't exist along its length.

> It is the di/dt along the radiator length that
> generates those fields.

Yep, and a short antenna has a much higher I and therefore di/dt for a
given power input than a long one. The result is the same total field.

> Adding a matching network at the antenna input doesn't change the
> instrinsic
> ability of an antenna to radiate.

Correct.

> That is determined by the factors
> described in the paragraph above.

I don't believe the factors you cited play any role in determining the
ability of an antenna to radiate.

> A matching network can permit the tx to
> increase its rated, safe output power while driving that poor antenna, but
> any extra power available at the antenna input because of that will be
> subject to the same poor radiation efficiency as if the matcher wasn't
> used.

Why "poor" radiation efficiency? An antenna radiates all the power it's
supplied, less the amount lost due to conductor and insulation
resistance. While it's more difficult to make a short antenna efficient,
it's not impossible. There's no loss of radiation efficiency directly
due to the length of the antenna.

> And much of any added power from the tx may get dissipated in lossy output
> system components other than the antenna, rather than being radiated.

That's correct. An antenna system which includes a short antenna is
likely to be less efficient because the short antenna's impedance
requires greater transformation than a longer antenna's, and this is
difficult to do with high efficiency. The loss of system efficiency (as
opposed to antenna radiation efficiency) is due to loss in the matching
network components.

> The
> antenna itself will still have the same directivity/gain that it had before
> the matching network was added.
>

Correct.

> Improving the ability of a poor antenna to generate EM fields per unit of
> source power is possible in a limited way only by increasing its electrical
> length.

Sorry, that's completely wrong. Try modeling a half wave dipole in free
space with the EZNEC demo program, then model a very short dipole, say

0.01 wavelength long. For both, set the wire loss to zero. You'll see
that the gain is only about a half dB different, due to the slightly
fatter shape of the short dipole's lobes. An Average Gain check, which
compares the total power in the field with the power fed from the
source, can be used as a direct measure of the radiation efficiency. It
should be very close to one for both antennas. (Any deviation from one
is due to calculation imprecision in the program.)

These EZNEC results are correct. If you have trouble believing them,
I'll be glad to furnish you with a few references from well known textbooks.

Of course, an actual antenna *will* have wire loss, and the wire
resistance will cause more loss in the short antenna than in a longer
one, due to the higher current for a given power input. It's that, plus
the matching system loss, that causes real short antennas to often
perform poorly -- not something inherently due to the generation of the
field from a short conductor.

> "Capacity hats" and inductances incorporated into the radiating
> structure can be used, as examples. This also raises the antenna radiation
> resistance and reduces the reactance at the antenna input -- making it

Don't know about MFJ's but I went to Lowes Home Improvement and bought one made by Channel Master and its good and strong.

Why do so few correspondents on newsgroups give their real names and
call signs?

Why the hidden secrets?

People should be proud of their call signs.

Or do radio amateurs suffer from inferiority complexes.

Back to SWR.

Reg, G4FGQ

Most antennas are NOT a circuit. Most antennas are distributed
networks.

Circuit theory doesn't work on distributed network problems.
That's why distributed network analysis was invented.

i have made a modification to it, it is now 1/4 wavelength monopole.
the simulation output is : source voltage= 3092 at -89.79 deg. and
impedance= 11.08-j3092 ohm . what is the meaning of this source
voltage? i have placed a source with amplitude 1v at 0% from E1 because
it is a monopole, the ground type is free space.

Sounds like the source is one amp, not one volt.

Yes the majority of hams are indeed interested in Local HF communications
on 80 & 40. Something that will reliably commutate out to 300-400
miles.

When they think of DX they think 20 - 10 meters.

Those that are interested in DX on 80 meters are a very small minority.

They can get that from a 40 ft. high G5RV. No 7' high
NVIS dipole is needed. AND you can work DX on 20m-10m
with that 40 ft. high G5RV. I repeat, the majority of
hams are NOT interested *only* in local communications
on HF. A 7' high dipole is a poor performer on 20m-10m.

Something must be wrong with your model. A resonate 1/4-wave monopole
should have the resistance component around 20-ohms or so.
Additionally, it would appear by the high reactive component you give
that you do not have a ground plane included in you model. A 1/4-wave
monopole requires something to work against.

Reg:

That is a very legit question. While I cannot speak for everyone, I can speak for myself and why methods are employed which lead some to suspicion of those who cloak themselves in anonymity.

In my area, I am the only "free thinker" (for want of better word(s)) here (well, at least openly so.)

I enjoy radio right down to blackest pirates heart. I am as likely to be found chatting with a trucker on the chicken band as chatting with a person on the ham bands. I am aware of the "freebanders", however my "discussions" with them are best left undefined.

At 50+ years old, the hams are too old in thinking even for I. I have had them parked upon my street with their meters, doing calculations on my power for the different bands in question. I have had harassing phone calls from them, mail, and e-mail as they accuse and threaten what they term my "illegal activity."

I am fed up with the whole lot of them. My course in this world is my own. I am courteous and enjoy EVERYONE being able to communicate--I would never knowingly or willingly stop, hamper or attempt to hinder others and their hobbies. Unfortunately, I have not found the same in others philosophy. I am outspoken, I will tell my opinion right up front--I have respect for other men doing the same, they need not agree with me, nor I with them--I find more importance in truth than in sugar coated words.

Because of my philosophy, and a vast number in disagreement, I have had my station here checked out twice--I passed in both instances--but don't wish to provoke a third. It is obvious to me that someone, probably some group (a bastard and all his friends and "good buddies.") has been the cause of this... and while I don't suspect the CB'er and freebanders, I now hold much caution around hams...

It ain't pretty--but is truth... and you did ask...

Warmest regards,
John

Do you have your ground planes separated from the radiator in the model?

Do you have the source placed at the bottom end of the radiator?

Perhaps one more versed in EZNEC would take a look if you would
post/offer the antenna file you have created here...

I'm sorry to disapoint you, but that's what everyone who can't hold down
a job says. The same people when rejected by the army say they are in
a "secret unit", very hush hush, etc.

In reality, the real people who work for the mossad don't tell anyone. In fact
the head of the mossad was never published until about 2 years ago.

Geoff.

IMHO a Bird meter is overkill in this situation. It's a bit like
recommending
a Rolls Royce for doing the weekly shopping. It will work, but so will a VW.
There are any number of
perfectly adequate meters from a wide variety of manufacturers at prices
considerably below that of a Bird.

Bob:

I would like to think my neighbors enjoy me. I would like to think they would describe me as a man which can get along with anyone, is helpful, kind to women, children and animals--a danger to no man--and willing to help all--the type of individual one would like for a neighbor.

And, unless threatened with death, bodily injury or to be deprived of my property or pursuit of happiness, I will NOT move a hand to stop any--I gauge none, if their pursuits make them happy and are of no danger to anyone else--I will generally support those endeavors.

From the general demeanor my neighbors and fellow citizens reflect towards me--I think I am at least partially successful in my attempts to be an acceptable member of society.

I would even like to think to I am an asset to my community rather than a hindrance, burden or drain...

If some would still find me a "criminal" after I have fulfilled the obligations and responsibilities as I have mentioned above--then so be it...

... some of my personal pursuits I engage in are of a private nature and an exact description will have to be foregone.

Mind you! The above is not to be taken as an admission that I masturbate in private!!! <grin>

Warmest regards,
John

I have a spare Bird 43 meter with the Peak Modification (your choice of "N" or UHF" connectors) and the leather carrying case that I could sell you for that price.

This came out of Cellular industry component repair shop (Condition is virtually new - described as "very good")

You would need to purchase the appropriate Bird Element for the Frequency and Power of the radios you use.

Message-ID: <11ap2hu85h9ht52@corp.supernews.com>
Source record: 75039

Antennas *are* circuits. Circuits can consist of either lumped or distributed components, or both.

However, that's not particularly relevant to my point. In the steady state, there is no test which can be devised that can distinguish an antenna (including feedline, if desired) from a black box containing lumped components -- a lumped component circuit(*). This allows us to simply design such things as matching networks without any consideration of the real properties of an antenna. Only when transient signals are involved is other than simple lumped-network analysis necessary. In a typical antenna and feedline system, steady state is reached much, much faster than even the fastest CW dit or speech component, so transient analysis isn't required for these common modes of operation. There are a few familiar situations where analysis under normal operating conditions requires consideration of the distributed nature of the system, such as when doing time domain reflectometry or in some situations involving television signals, both modulated and baseband. None of these, however, can be considered steady state so the simplified model isn't applicable.

Cecil, if you feel a need to expound yet more on your theories, please do so in one of the many threads you've come to dominate already, start a new one, or concentrate your efforts on your forthcoming QEX article. I hope you'll let us try and make an objective and hopefully helpful contribution from time to time on this newsgroup without your constantly attempting to steer the discussion to your theories.

(*) Furthermore, if we restrict analysis to a single frequency, the black box needs to contain only two components - a resistor and either a capacitor or inductor.

Coming from, and living in, a rural culture where people are individuals with names, it is difficult for me to give weight to the emissions of those without a real name or call sign.

Not to place one's name on one's work is to place no value on it. It is irritating to see so much that is written here being given no value by the author.

Some of the most verbose are sounding brass and tinkling bells signifying nothing.

My opinion. My (only) name.

Cecil, since I started this thread with a comment on yours, in retrospect
I will admit what you say above is true! My comment applied to a small
particular group of operators on the lower bands (or is that higher bands?)

J. Mc Laughlin:

That is certainly an open and honest post, which gives deep insight into the authors mind...

It is obvious that only your close family, friends, fellow employees and local community have any "real" weight on your considerations and efforts...

While that is fine, it would be better if you did not place yourself in a position where you have influence over others you "have not met/don' know their name(s)"... as, even for your ignorance of them--they are just as important--in some instances, it is even to imagine them of even more importance...

... but, once one can verbalize their limitations they are in a far better position to deal with those limitations and not suffer others for their lack thereof...

Warmest regards,
John

I certainly don't consider a Bird watt meter to be a "Rolls Royce" in the communications maintenance industry. If you look at ANY two-way radio maintenance shop, you will most likely find a Bird watt meter being used on a regular basis. Its more like a "Chevy" than a Rolls!

The guy is looking to do maintenance on a fleet of unknown number of busses. I recommended an instrument he can trust, and that will hold up to a considerable amount of physical abuse. So, if you think the Bird is too much, what are your suggestions for this guy?

Hello, Roy & the Group.

One think you may have missed, the original post was about a Arrow Antenna J-Pole. This is an Open Stub type J-Pole, Not a Closed Stub type like the copper pipe ones. The OSJ does not need a choke, it does not have a problem with feedline radiation or a problem with Common Mode Currents.

> In the typical J-pole antenna, the shield connects to the long element
> and the center to the stub. I don't know your antenna in particular,

The OSJ is not a typical J-pole.

One final comment: this thread shows how difficult it can be to distil a complex subject down to a few paragraphs, without making generalizations that will sometimes be incorrect.

It can never be done in a single pass, so all credit for making the effort and for taking the comments on board.

I know very little about this, but a few months ago I was fascinated by a half hour program about the history of the Corvette on public TV. (It's one of a series.) Turns out that the first couple of 'vettes weren't muscle cars at all, but gutless wonders with a small engine and two-speed automatic transmission -- it took a while to evolve. I don't recall for sure, but think it's likely those were metal.

Hi Reg

It is indeed very simple

Once you post to this NG it is publicly available to anyone and anything that has an internet connection. Data about you can be farmed, correlated and remarketed. If you have trouble believing that do a Google on your callsign in NG's and see how many hits you get.

Even if one posts with a callsign (which I do) it is then easy to cross reference that to a govt database containing home address etc details. I dont have an issue with people not posting their callsigns for this reason. If personal contact is needed it is very easy to ask and I have never had a problem in doing so

Between me and the other experimnenter/hobbiests in this NG I have no problem with my identity or pride thereof. It's the "dark unknowns" <grin> I have the problem with.

Cheers Bob VK2YQA/WA5 Longview Texas (in 2 weeks anyway!)

Hi Ed -

I have never seen one of the MFJs, but I was also interested.

When I asked about them at my friendly local HRO, I was told
that they're as flexible as a fishing pole near the end, and that
I probably wouldn't be happy if I actually tried to hold anything
up with one. Although disappointed, I took their word for it,
and passed.

I was hoping we would not have to go through this AGAIN.

The typical J-Pole (Closed Stub) was designed to feed with open feed
line. Because Hams insist on feeding it with coax, a Band-Aid is
needed to choke off feed line radiation & common mode currents.
The Open Stub J-Pole was designed to feed with coax. So it don't need
the Band Aid.
The difference between the two is discussed in several antenna books.
Just ask anyone the owns one.

redhat:

I don't want Roy jumping me about giving advice on his application...

However, you need to give the starting height of your elements some distance above ground... actually, you would be wise to really make this a "real" value, like the actual height the antenna will be...

... for example, say you have an eight foot long vertical radiator at ten feet above ground--then one x,y value will be 10.0 and the ending x,y value will be 18.0...

I hope that is clear enough, Roy Lewellan would best be consulted on EZNEC's exact workings...

For exactly the same reason that you need a choke on a ground plane or any other antenna feed with coax. Depending upon the length of the feed line common mode current can be substantial. This, in turn, increases higher angle radiation. Now if you are most interested in talking to airplanes that would be a good thing, but if you prefer maximum signal towards the horizon then put a choke on that sucker!

Danny, K6MHE

946. Re: monopole Design

Newsgroup: rec.radio.amateur.antenna

From: redhat <aezzat1@gmail.com>
Message-ID: <1118617083.981637.118340@g49g2000cwa.googlegroups.com>
Source record: 75058

the ground was set to "free space" and when i selected "perfect" ground

an error occured "one or more wires extended into or lying on the
ground", the problem was that in the wire coordinates z was set to 0
,when i selected a different z the problem was solved but the voltage
is still high, the antenna will be placed 90 deg. to the ground plane
so what should be z value?should it be the same length of the antenna?
the source is placed 0% from E1 (monopole). the pattern of the antenna
shows a gain of 1.5dbi ,if i have a circuit that outputs 2db for
example then the output from the antenna should be 3.5db, right? or
because dbi is referenced to isotropic source there is a conversion?
note: i can't upload the file rightnow

You can't distinguish between a resonant 1/2WL dipole and a dummy load
using a field strength meter? :-) You can't distinguish between a
dummy load impedor and a resonant dipole impedance? How about just
looking to see if a physical impedor exists? Those two impedances even
have different definitions in the IEEE Dictionary.

Their not my theories, Roy. For instance,
the IEEE Dictionary distinguishes between the (virtual) feedpoint
impedance of a resonant antenna and the impedance of an impedor,
e.g. a dummy load. Those two impedances have *different* definitions.
A dummy load impedor is the *cause* of the load V/I ratio. The
resistance of a resonant 50 ohm antenna is the *effect* of the
feedpoint (superposed-V/superposed-I) ratio. Isn't it past time
for completely ignoring cause and effect?

>By open stub, you mean there is no loop at the bottom of the "J"?

>bob k5qwg

No, Open Stub means the 1/4 wave element and the 3/4 wave element are
not connected.

In the typical (closed stub) J-Pole I have seen the center of the coax
connected to ether side of the antenna, seems to work equally poor
ether way.

In the case of the Open Stub J-Pole I have found that a wider bandwidth
can be obtained connecting the center to the 3/4 wave element. (about
12 MHz.)
Connecting to the 1/4 wave element, bandwidth is only about 6 MHz.
The 2 meter band is only 4 MHz. so it really don't matter too much.
Try that with the typical copper pipe J-Pole.

The top band is considered to be 160m so I assume "band" is
associated with wavelength, e.g. "160m band". So it appears
that higher bands = lower frequencies, but I could be wrong.
The IEEE Dictionary is no help. It thinks a "band" is a
track on a rotating memory device. :-)

> 73 Al Lowe N0IMW

Sorry, I didn't realize we'd been through it before. If you'll tell me the date, I'll look up the postings and review them.

There are two things which can cause current on the feedline. One is by conduction. That mechanism is illustrated in Fig 21-1 at http://www.w2du/r2ch21.pdf, and elaborated on in http://eznec.com/Amateur/Articles/Baluns.pdf. Some types of feed systems can minimize this, and it looks like both the open and shorted stub feed systems are in this category.

But it's the second mechanism I was talking about -- mutual coupling, or induction. Even if you have a perfect current balun (common mode choke) at the feedpoint or any sort of feed system you want, current can still be coupled to the feedline. In a center fed dipole, it won't occur if you first make sure there's no conducted current, and place the feedline symmetrically relative to the dipole to make the coupling from the two dipole halves cancel. But you can't do this with a ground plane, J-Pole, or similar antenna -- there will always be coupling from the antenna to the feedline. Fiddling with the feedpoint won't prevent it, although it might change the current distribution on the feedline. Changing the feedline length and/or orientation and/or using a couple of current baluns spaced about a quarter wavelength apart are two ways it can be minimized.

I'd be interested in seeing any book which explains how a feedpoint modification can prevent current being coupled to the feedline (as opposed to being conducted).

953. microwave oven magetron + pringle can antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-12 23:11:55 UTC
From: Anchor <anchorelectronics@sympatico.ca>
Message-ID: <pan.2005.06.12.23.11.54.893920@sympatico.ca>
Source record: 75073

Any suggestions on how to build a 2.4 GHz CW transmitter with a microwave oven magnetron and a 2.4 GHz "pringle" or coffee can style antenna?

There are tons of "pringle" or coffee can antennas or similar on the web. For example: http://flakey.info/antenna/waveguide or http://www.turnpoint.net/wireless/antennas/mycoffeecan.html

I suppose one need only insert the magnetron antenna into the coffee can where one would normally mount the N-connector feed point.

A labeled diagram of a microwave magnetron can be found at: http://www.gallawa.com/microtech/mag_test.html

I suppose the metal coffee can has superior micro shielding properties relative to the aluminumized cardboard pringle can.

Would I be better off with plumbing copper drain pipe from the stray RF exposure perspective?

Since microwave magnetron use a half wave power supply, can I use two magnetrons in the same coffee can powered from a single AC HV transformer with a pair of HV rectifiers to feed alternate cycles to the magnetrons?

I agree with the choke needed on a ground plane. But all antennas ?
Sure you can put a choke on a OSJ won't hurt, won't help ether.
Been there, done that.

Don't know about the body but it had virtually the same 6 cyl
engine and transmission as my uncle's 1955 Chevy Bel Aire.
Chevy introduced the V8 (350 in^3?) in 1956 and that's when
it went into the Corvette and into all those Chevys that broke
all the records that year.

He means the bottom of the stub is the feedpoint, like this:

```
+-------------------------------------------------------------
|
FP
|
+-----------------
```

And that looks like an unbalanced feedpoint so it should result
in common-mode currents, sorta like an off center-fed dipole.

The Corvette was introduced in 1955 with Chevy's old straight
six engine. I remember it in a Mike Hammer movie, "Kiss Me Deadly".
The 1956 models got that first short stroke V8 which was the
grandfather of the engine in my daughter's 2003 Chevy Tahoe.

I don't remember if you were involved or not Roy. It's been about 10
years ago.
One I remember is Tom Raunch (hope I spelled that right).
We argued for weeks about the OSJ until I sent him one.
Some tried modeling it, some even claimed it would not work at all.
The OSJ has been around for a long time, I did not invent it, I just
build it better.
I guess all antennas have feed line radiation and/or common mode
currents to some degree.
I suppose with the right equipment you can measure anything.
But I think most would find a big difference between an OSJ & a CSJ
Just because two antennas look similar, don't mean they work the same.

Ok, that was fun, But I have wasted enough time, I got to get back to
building Antennas.

The 327 was not offered tuil the 1962 modle came out. The 350 engine was still later. I think it was the 1967 or 68 when the 350 engine was offered in anything. In 1955 it came out with a small V8, the 265 which was the basis of all the small block engines of that series. Also I think that was the first year they got away from the 2 speed auto transmission and offered a manual transmission. The six cylinder was basically the same as in the other cars but it was setup to produce more horespower than most other modles of that era.

The July 1989 73 had an article on using a microwave oven for ATV. It
involved keeping most of the oven intact (including interlocks), with a
blocking plate over the opening between the magnetron and the oven
cavity and an e-field probe to couple the output to coax.

Beyond that I know nothing.

And he's off again. I gained a lot of peace when I put "John Smith" and Jesus as the very first two entries in my filter list some time ago. You now have the distinction of being the third -- just below Jesus.

It's really a shame -- on those rare instances where you can be coaxed into commenting without being compelled to steer the subject to your favorite obsession, you really do have a lot to offer. But the duty cycle is just too low -- it's not worth it to me. Bye.

Allow me to repeat: *ANY* antenna feed with coax should employee a
choke. It is just good engineering practice.

If your beloved open base j-pole is feed with coax that is any
multiple of a 1/2-wavelength you ARE GOING TO HAVE HIGH COMMON MODE
CURRENT!

So just what makes you beleive that your open base j-pole has some
magical properties that is self-decouples itself from the feed line?

Duh, I had a '54' vett with a stock six-banger, that was stock from the factory with a mostly fiberglass body..

The '55' vett's had a 265 cu in v8 and went quite a bit better.. 56 vett's still had the 265 and it wasn't until 57 that they changed to the hotty 283 with fuel injection and duntov cams.. Then they really went like stink shit!

Try this telescoping mast from DK9SQ via US Dealer -- Kanga
http://www.bright.net/~kanga/kanga/dk9sq/mast.htm

Lot sturdier than MFJ -- we used one for a 20M inverted vee at field day

Or a tail gate flag pole
http://www.flagsexpress.com/poles/pole_04.htm

I use the 20 footer coupled to a swimming pool pole to make a 32 foot
vertical for field day
Uses four 32 foot drooping radials. Tis flat across the entire 40 meter
band -- works on 15M of course

--
CL -- I doubt, therefore I might be !

There have been some replies which provide good reasons (spam & crank avoidance) and some lesser reasons (fear of data correlation and/or "big brother" snooping) to hide one's identity.

OTOH, I have found that familiarity encourages and supports civility. Maybe the human psyche needs an occasional Halloween, Day of the Dead, Masquerade Ball (or whatever your local culture defines) as a safety valve. But on a daily basis, I am quite uncomfortable with being asked to talk with someone who feels the need to cloak their identity.

Thus, if you identify yourself with something like Wonkawonka or AntennaWizzard, you place yourself at a disadvantage in my opinion of you. You will have to exhibit true and consistent brilliance and honesty to climb out of my initial negative evaluation of your worth.

You have a choice to identify, and I have a choice to form an evaluation of your choices. How could anything be fairer and more fun?

Hi OM,

As I pointed out some time ago, your work is very far off track.

It would be far simpler to start with a working design and change it
slightly to observe how your input effects the results.

Simply hit the Open button and select:
VERT1.EZ
and look at ALL the characteristics. This may mean starting a
notebook (standard Engineering discipline) and logging those values.
Make a change (like shorten or lengthen the ONLY wire) and look at ALL
the characteristics. Log those values and compare to the first.

Keep doing this and eventualy you will find that
>the velocity factor of the wire
is not very significant - or better yet, discover what significance it
has (it will eventually become significant, but not practically so)
and report your results here.

Ed:

Yes. Much difference in ones "attack upon the world", I respect your right to having yours, please respect mine...

I always enjoy going to new places and meeting new people. I have no apprehension of people I don't know--if they are interesting I will attempt to know them--if not, they are best left as is...

My anonymity servers me quite well... I wish no recognition for my call, my name, my age, my birthright, my bloodline, etc...

I do not seek to know others identity, a nick is good enough, I will judge their words upon the words use to myself, and if the individual is able to formulate it in a method which is conductive to being understood simply (quotes of Shakespeare fails this test)... although others state different methods in handling this and, while I will refrain from judgment in using other methods, my methods have served me well for many years.

Frankly, I have nothing important to impart to anyone--I have my observations, views, beliefs, methods, etc... but I am here to pick up knowledge rather than give... I am NOT an antenna guru... I study the humble 1/2 wave vertical in great detail simply because it if of use to me... if I offer "what I think I know" and it is in error--well darn, what a perfect excuse to get the proper knowledge out, don't you think? I am sure someone will correct it...

If you think me a danger and wanting to do "ego battle" with those egos here big enough to fill a room--I am not, if you don't believe me, wait until I give you reason to reprimand me and at that time give me a good "butt kicking."

I DON'T think even the simple antenna is well understood... that is in having a "complete understanding" of it... I will use what formulas there is available and be darn thankful they work as well as they do... however, I think there is more to all this than meets the eye...

And what can I say, I believe in the ether. If that opens me up to ridicule and having fun poked at me--so be it... actually, I wish to know more about it than the metal contraptions men build to interface with the darn mysterious stuff!!! I am disappointed no books I have found deal with it in a meaningful way which has practical implications to them...

And, on my failings, I can have a "sharp tongue", but don't fear it, it is only a tool to provoke meaningful thought and discussion--I have no

real interest in abusing others with it--abusing others does nothing for me--I'd sooner have a friend than an enemy... but if ideas must be gained in an adversarial forum--again, so be it...

I am a geek that likes quiet places and to think, really, all I want to do is think and build models in my mind... I also just happen to like to experiment with antennas...

Warmest regards,
John

What are you disagreeing with? How much DX do you work with
your NVIS antenna? Do you really think the majority of hams
are only interested in local communications on HF?

Some are...Most work only the low bands...I know many
hams who couldn't care less about dx. They only talk to
other regional "good ole boys"....
But saying that, comparing a G5RV at 50 ft, against a
dipole at 7 ft, is fairly silly. The NVIS qualities are more
due to height above ground per wavelength, than the
length of the antenna.
Overall, I think the idea of running low dipoles, or using
ground screens, and pseudo "reflectors" etc, are
generally a waste of time.. If I were working NVIS on 75m,
I'd prefer a dipole at 50ft over one at 7 ft. It will have lower
ground losses, and I'd be willing to bet the NVIS performance
would be just as good as the low antenna. But, the medium
range performance would be a good bit better. Also, you
can work dx also...I've worked dx on 75m, using a dipole
at 35 ft...It's no big deal really...Just finding the DX to talk to
is more difficult. Also...NVIS antennas are not low noise,
unless they are defective in some way...They may reduce
the reception of far off lightning, if that static arrives at
low angles.. A low dipole has great reception of noise...
Straight up....A low to medium height dipole already has
enough gain straight up. I don't really want to enhance it
further...I also want to have decent performance on longer
paths...Listen to all the BIG strappers on 75m...I bet very few
are running real low dipoles with screens...Most will be running
higher dipoles hung from towers, trees, etc...

Would you agree this is a 2m Zepp? Zepps are known to have
common mode currents. We know the current at point 'x' is
not the same as the current at point 'y'.

in designing a monopole should i use the velocity factor of the wire
in
the equation or not?

No...It's silly...Do you check the VF of wire when you
build a dipole? It's overkill worrying....The VF of straight
wire is in the 95+ range...Not enough to worry about...

and if i want its impedance to be 50ohm should i
use a matching network or is there another way?

There is no other way. If you want to build a 1/8 wave
vertical, build it the same way you would build a mobile
vertical. If not top loaded with a hat, you should use a
loading coil at 1/2 to 3/4 up the vertical for best efficiency.
You would use a matching device of the same type used
for most mobiles. If you want to tinker with vertical design,
I'd try something like Reg's "vertload" to design the antenna.
It will tell the appx efficiency of the design, and also give you the
values needed for a matching device, which can be a simple
coil or cap depending how you set it up. Then, after that is
done, you can try modeling it. Short vertical design is quite
mature...You are not going to be able to reinvent the wheel...

As you may have missed previously, my comments were directed from the standpoint of a 75M/40M operator. Personally, I don't consider a NVIS antenna a valid antenna above those bands. So, for the two bands I have in mind, Yes, I believe the majority of operators there are interested in local/intra-state communications.

Ed

>
>Is that possible, or hype?

I'll take a stab at it. First of all, its objective is to create
nulls at low-take-off angles so shortwave broadcast stations will not
have so much noise. The antenna is a 300 ohm folded dipole that is
fed with 50 ohms but then the antenna has a reflector on the ground.
It is effectively a 2-element yagi pointed strait up (give or take a
few degrees at the user's choosing.)

I don't think a two element beam has a 10 db gain, but I don't know
the gain of a G5RV on the same frequency. Presumably, the signal
strength of local signals will improve and DX or broadcast stations
will drop.

This is known as a Near Vertical Incidence (I forget the 's') antenna.
Great for operating local districts on 160-30 meters. If the dipole
is raised high enough, it will be just a dipole, but then it will be
mis-matched to the feedline and have considerable loss.

This is my theory, correct me if I am wrong

987. Antenna @ speed of light...

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-13 06:08:00 UTC
From: John Smith <assemblywizard@gmail.com>
Message-ID: <1p9re.84$lv3.5397608@news.sisna.com>
Source record: 75155

I pictured this, I am in a spacecraft doing the speed of light, I key the xmitter and begin a long winded rant, the antenna is monopole.

Now the signal leaving the rear of the antenna appears to be leaving it at 2X the speed of light (allowing for the VF of space-ether), however, the signal off the very front, at least the width of the antenna conductor itself, cannot leave (since I am traveling at the speed of light the signal appears to just stay on the surface of the conductor)--what will happen?

Warmest regards,
John

Not quite. Look closer - http://www.arrowantennas.com/j-pole.html
You assume it should result in common-mode currents.
And you know what happens when you Ass u me.

But....Common mode current on the feedline can't be avoided
no matter how the antenna is fed. I agree that the antenna is
quite usable without decoupling, and I've found that the 1/2 WL
ringo's usual "gamma loop" feed is also fairly good as far as that.
But there is no way to totally avoid all currents, without some form
of decoupling. If you believe you can, try some tests adding decoupling
sections. If you don't see an increase in performance, I would
be *very* surprised. In some cases, it's possible for the currents
to add, and produce a gain at low angles, but it's fairly unlikely.
Most of the time, the pattern is skewed upwards. It takes at least
two decoupling sections to fully decouple an elevated vertical.
To me, you have none, although maybe you could argue that your
feed of feeding qualifies as a first decoupling section...Lets say
you win, and this is the case...You still need one more, if you
want to be fully decoupled... If you believe you are now, I'd be
willing to bet you are deluding yourself.
Thats not to say the antenna doesn't work ok as is...I'm sure it
probably does, except the most retentive of users...I've used
loads of halfwaves with no decoupling...But those were all on 10m,
where it's not so critical. BTW...The results of adding decoupling
sections will vary from user to user, depending on their lines.
But if the antenna is totally decoupled, the amount of current will
be the appx same for any user, no matter feed length.
When I say total, I mean as much as practical. I don't believe you
can totally eliminate all current. There will always be a small
amount.
I doubt I would change the antenna....Would make it cost more...
I'd consider a super deluxe version for a higher price, if they wanted
full 2 section decoupling...:/ And if I went that far, I'd use a dual
5/8 design to get more gain. You'd be reinventing the isopole...:/

>and passed.

If the MFJ is like the DK9SQ pole, it will be very flexible at the top. One section down from the top, at about 29ft, the DK9SQ *will* hold up a G5RV - but only if the whole antenna is ultra-lightweight.

Don't even think about the typical #14 dipole with big, heavy insulators! The pole won't hold one of those above the 20-25ft level. My GM5RV/P is made of thin hookup wire with a lightweight center insulator (a small plastic box that drops over the top section). End insulators are simply the monofilament fishing line that continues on down to the tie-offs.

Obviously the pole will bend over at the top, and it's an art to get everything tied off and tensioned just right. You have to accept that the whole thing will wave around in even the slightest breeze... but it will also ride out a full gale.

If you want these poles to stay up, you have to twist each joint into place as hard as you can, and fix it with PVC tape. If you don't, the back-and-forth leverage of the wind will loosen the joints, and then the top part of the pole can slam down into the lower part causing damage.

But having said all that, these flexible lightweight poles can get a temporary inverted-V into the air in places that would otherwise be impossible.

Has anyone tried the new 40ft pole from Spiderbeam in Germany? This looks much better: http://www.spiderbeam.net then click on "Heavy duty fibreglass poles".

Message-ID: <Hqcre.88$zR5.5895276@news.sisna.com>
Source record: 75157

Ok, no takers so far, and since I am having trouble sleeping...

I remount the xmitter in the space craft...
Now the rear of the xmitter is facing the rear of the spacecraft--and
the antenna just happens to be back there at the rear of the spacecraft
too... we continue at the speed of light...

But now, the signal is shot through the coax at 2x times the speed of
light (due to its speed through the coax, combined with the fact that
the coax is traveling at the speed of light and the signal travels in an
opposite direction through that coax)... the signal now strikes that
antenna at 2x the speed of light and is able to leave the front of the
antenna at 1X the speed of light! ...or, does it?

But, suddenly I notice a problem at the front of the spacecraft and, it
is dark up there... no problem, I grab my trusty flashlight, point it at
the front of the spacecraft and turn it on... but, big problem, the
front of the spacecraft remains dark... I move the flashlight and notice
a bunch of light photons hanging in the air right where I had been
holding the flashlight... unable to overtake the speed of light I am
traveling at!!! Indeed, it is getting pretty darn bight inside this
spacecraft now, as no forward light is able to travel forward and be
reflected or absorbed...

My co-pilot suddenly says, "That is impossible! The flashlight is
traveling at the speed of light, any light it gives off has to be
traveling at 2X the speed of light and can go forward--those photons
cannot possibly be there hanging in midair!"

To which, I respond, "Nothing can go faster than the speed of light,
fool!" <grin>

(I just threw in the "fool" for effect... the co-pilot knew I was
kidding)

... maybe I can sleep now...

Warmest regards,
John

a pringle 'can' would probably arc and burn up. i would really worry about side/rear lobes with coffee can antennas, even a minor lobe when working with kw levels at those frequencies could do some real damage in a short time... and reflections off nearby objects of the main lobe could really do a job on you. remember what those things are meant to do and be darn sure you don't end up looking like a bag of popcorn.

The Doppler effect doesn't change the speed of light, only
the frequency. All EM waves appear to all observers to
travel at the speed of light.

>(allowing for the VF of space-ether), however,
> the signal off the very front, at least the width of the antenna

It doesn't appear that way to you. For you, time has stopped
but you don't know it. You also possess infinite mass and occupy
zero volume but you don't know it.

>(since I am traveling at the speed of
> light the signal appears to just stay on the surface of the
> conductor)--what will happen?

It would make more sense to assume that you are traveling at
1/2 the speed of light and see what happens. Future humans
may be able to do just that. Assume you have a twin brother
back on earth QSOing with you. He's transmitting in a ham
band. What frequency do you hear him on?

Why don't you move the source to the bottom (ground) end of the
monopole? I'm guessing that E1 is the top of the vertical.

Use "View Antenna" to see for sure. You can use Z=0 if you use
MiniNEC ground.

And here I was, wondering what the problem could possibly be.

Careful Roy, you're goring a commercial ox.

Al, you have some really ingenious machinery and your products look to
be well made. But you should probably stick to machining and hire two
more folks: one to do antenna design and another to write copy and
manage your web site.

With just a cursory look I see that you sell "beems" instead of
"beams" and a claim that corner reflectors work better on packet than
do Yagis is pure snake oil.

Simply modeling your super J-pole and adding a third element to
represent the transmission line would show that the line radiates like
crazy and affects the feedpoint Z.

That statement is generally correct, however, if you were to use a bead balun things change a bit. The reason being that on 2-meters the balun is about 10" long (about 1/8-wavelength). When model correctly, you can observe that such a balun is pretty good at choking of common mode current without resorting to adding a second one.

It works even better on 200 MHz and 440MHz.

Actually, standing on the earth we are already moving at over 1,000 mph.
If you point a flashlight in the direction of rotation--it has the
potential of +1,000 mph than when you turn around and point it west.

Also, the universe is expanding, and that is pushing us on at a good
clip. Funny you don't see this being taken into account anywhere except
on space launches... but I have noticed what looks like a speedier
launch in one direction of my monopole, as compared to the other...

... most notably, when my ant is at an angle 90 degrees to the combined
directions of both the rotation of the earth and the expanding universe
direction... <grin>

Warmest regards,
John

I never said anything about a "super J-Pole" .
Other than maybe it is super simple.

If you simply modeled the OSJ and it showed the feed line radiates like
crazy, Maybe you didn't do it right. Maybe you need to step out into
the real world.

By the way, it has a 3rd element, makes it a dual J-Pole not just a
dual band.

There have been interesting replies to my original query.

But for some reason I cannot explain, I feel much more comfortable
when I receive a message with a signature like "Buck, N4PGW".

At least it conveys the additional information you are located
somewhere within the few million square miles of the United States of
America.

I get as much pleasure as when messages are received from New Zealand,
down-under, and what used to be the USSR and from China.

Reg, G4FGQ

They who discuss "power radiated from the feedline", yet are unable to measure (in watts) or calculate (in watts) the MAGNITUDE of the effect, belong to a set of waffling old wives.

How is it possible to decide whether or not a choke or balun is needed, and where to locate it, unless the magnitude of what one MIGHT wish to prevent is known.

Do we always, without valid reason, just copy the practical construction details from ARRL handbooks, on the grounds that if it once worked OK for somebody else it might work for me.

But of course, you'll never get to know, having copied a very simple system which contains a choke, unless you remove the choke and observe what happens to system performance. Or alternatively, add a choke if the ARRL handbook implies that you don't need one, and then make more observations.

My guess is that in many cases hardly anything will happen or be noticed. Simply because the MAGNITUDE of the effects due to line radiation is too small to be of consequence or detected even.

If you can't measure or calculate the MAGNITUDE of the effects, stop worrying about it.

The frequency at which "radiation from the line" is mentioned in this newsgroup is out of all proportion to its importance. There's a tendency to drag it into the discussion because it is the last of the few remaining technical topics available to argue about. You have at least heard about the subject in the magazines.

The very last, of course, will be SWR. Because there is a meter which supposedly measures it but doesn't. And it is difficult to argue against meter users, such as Bird, suffering from delusions of accuracy, who are invariably convinced they are right.

Al, you could get a relative measure of common-mode
current by slipping a #68 toroidal pickup coil over
the coax.

Nope, that's not true. You will measure no difference. An observer
fixed compared to your position would measure a Doppler frequency
shift but no difference in velocity.

But it is taken into account. Most astronomers don't believe the
red shift is pure Doppler effect.

Agreed, but it is small enough I don't think most people could see a
difference in performance if it had a choke or not.
All I am saying, to say the antenna won't work with out a choke is just
wrong.

>I doubt I would change the antenna....Would make it cost more...
>I'd consider a super deluxe version for a higher price, if they wanted
>full 2 section decoupling...:/ And if I went that far, I'd use a dual
>5/8 design to get more gain. You'd be reinventing the isopole...:/
>MK

I have an "Isopole" here in the shop, it works good, maybe one of the
best
5/8 wave antennas I have ever tested. I think it could be built a
little better.
I have seen a lot of them that were broke.
But that is comparing apples to oranges
The OSJ is a simple 1/2 wave antenna that has 0 dBd gain.
No magic.
Again, I just think it is wrong to tell someone the antenna won't work
with out a choke.

Those who take no precautions to prevent their feedline from becoming part of the antenna, belong to a set of people who don't even know what their antenna IS.

There's a part you call "the antenna", and another part you call "the feedline". Wishful thinking will not stop RF current from flowing directly from one to the other.

>How is it possible to decide whether or not a choke or balun is
>needed, and where to locate it, unless the magnitude of what one MIGHT
>wish to prevent is known.
>
Try a clamp-on RF current meter, a little modeling... or even a little common sense.

There's a place called "the feedpoint" where the antenna and the feedline are connected directly together. Might that be a good location for a choke to keep them separate? Yes, it almost certainly would.

Chokes may also be needed at other locations, but it's hard to justify anywhere else as your *first* choice. (The exception is the Carolina Windom and similar antennas where part of the feedline is intended to radiate. But even there, they put a good choke at the point where they want RF currents on the feedline to stop.)

Queen Elizabeth 1 of England had the good sense to take a bath every six months "whether I need it or not". If you don't know whether your feedline smells of RF, then follow her excellent advice and use a choke.

I once looked at a microwave oven on a spectrum analyzer (Loosely coupled
near the door seal). The signal was spread over 100s of MHz. It also
appeared to be pulsed. The spectrum, however, did not look like the
expected
Sa(x) distribution. Magnetrons are not noted for their stability, and are
probably not suitable for CW. I have played with tunable 500 mW klystrons,
and they can drift 10s of MHz (at 12 GHz), in a very short period of time.

73,

Frank

Dave said:
"... all the errors in your logic when you start with impossible
conditions."

I certainly hope you don't mean "going the speed of light" as an "error"
of mine, we have already move "stuff" faster than that...

This article:
http://news.bbc.co.uk/1/hi/sci/tech/2049048.stm

claims the "teleportation" of a laser beam... now that IS occurring at
greater than the speed of light--else the beam would be gone before you
could get it moved!!!

... some of us need to remain current (I include myself in that
statement--I slip behind quickly)...

The far reaching repercussions of all this will not be realized for
decades...

Source record: 75085

Gentlemen,

Thank you for your responses. I appreciate the assistance.

It appears that I need to provide a bit more information to give you more insight into the circumstances I am faced with. I had hoped to keep both the question and responses as uncomplicated as possible. However, given the direction that a couple of responses have taken I see the need for expanded information.

It is true that I have substantial management experience, but it lies in a very different industry. In fact, for 11-years I owned a consumer electronics engineering/manufacturing company with sales in many foreign countries. During that time my company never borrowed any money and never carried any debt. Nevertheless, the time came to close the company and I did so. While it was not the easiest decision to make, it was the right one and the right time to do it.

I took a job last August driving school bus for a local barn for a large foreign-owned company, and shortly thereafter an opening for an operations clerk (glorified secretary), became available and I took it. (Yes, it's been humbling, but I have little room for ego.) It turns out that not only am I new in my position (as well as to the transportation industry), but the dispatcher and operations manager for the particular barn I work in are new in their positions as well. That is not to say that they are new to the company or to the industry. The operations manager has 9-years with the company.

I believe that part of my job is to help my superiors be successful and to look good to theirs. While I am hoping that other doors of opportunity will open for me, I have a responsibility to be as good an "operations clerk" as possible.

In this particular circumstance, I have come in long after the horse has escaped, as have my two immediate superiors. The issue with the communications amongst the 40 busses at this location is one that the three of us are attempting to clean up.

In terms of the rate charged, our mechanic gets about $15 per hour, while I get $9. Local auto dealers charge $45-$65 an hour. Therefore, using this as a reference $80 just seemed a bit steep. That said, if that is customary for UHF work then I will accept that as I said. Given the AP that I've seen, it seems clear that there is no service contract in place.

While the repairs made to the repeater did get channel 1 working again, it has a high static level with most but not all busses. A couple of

busses sound relatively clear, while most others are nearly unintelligeable. Channel 2 (direct) generally sounds much better across the board. However, even then many of the busses have problems. This is what leads me to suspect various antenna tuning issues. Therefore, my question about the feasibility of doing that in-house. I would much prefer to pay $15 an hour than $80 for the same work, but only of it makes sense to do so.

I hope that this provides more of the information that you gentlemen need to help me determine the most prudent course of action. I would like to be able to make a reasonably intelligent and informed recommendation to my superior. Thank you again for your assistance.

Mike

In the article I quoted above they tune the magnetron frequency by
varying the voltage to the magnetron. I wouldn't be surprised if the
oven's DC to the magnetron was filtered lightly or not at all.

If I recall correctly, Cebik has some discussion and modelling of such open-sleeve J-pole designs in his "Tales and Technicals" section. Start at http://www.cebik.com/vhf/jp1.html and go down about half-way.

The version of the "non-standard J-pole" which Cebik models is fed at bottom center, in a dimensionally-symmetrical way. His current plot seems to show equal currents at this feedpoint, and this would seem to make the use of a choke or balun on the feedline somewhat less significant than with a standard J-pole.

Cebik's model would need to be modified somewhat apply to the Arrow open-sleeve J-pole, as the Arrow is fed at the very base of the one element rather than halfway between the two.

Anybody care to model up the Arrow, with all three elements included, with and without a separate wire representing the outside of the coax?

I was just wondering if anyone had any comments on Comets new vertical, the CHA250B that was reviewed in this months CQ.

A reprint of the review can be found at:

http://www.benelec.com.au/pdf/Comet-CHA250B-Review.pdf

Seems a little pricey at over $430 (AES) but then again, a good screwdriver costs almost that much.

I wonder what kind of "Matching Network" it uses that it can be so broadbanded?

Let me tell you a little war story and see what you think.

About 20 years ago my boss, a newly minted PhD, got a job teaching a Senior/Graduate level course on Microwave Measurements Theory and Practice at the U of AZ. At the time the U's equipment was abysmal so he got permission to bring the kids into my lab at Hughes for the lab portion of the class.

I got the job of devising the experiments, setting up the gear and grading the lab notebooks. The kids could absolutely not see straight when I graded their grammar. Their cry was, "This is an engineering course, not an English course."

My reply was that they were prepping themselves for a job in industry (actually a few of them already worked at Hughes) and I wrote memos and reports every day, that if poorly written would reflect badly on me.

Your web site is your place of business...fill it up with typos, bad grammar and bogus claims and your business can suffer. On second thought, considering your client base, maybe they'll never notice.

Aha. So all I have to do is buy one of your antennas and write and tell you how awful it works and you'll put that on your web site.

>dual band.

No, I modeled the OSJVHF as depicted here:

http://www.arrowantennas.com/inst/igif/ijmurs1.gif

You claim 150-162 MHz with < 1.5:1 SWR. I modeled it as follows.

I saw the SWR vary from a low of 1.4:1 at 150 MHz to a high of almost
7:1 at 162 MHz.

Here's the file:

Hi Mike,

Your last sentence is what is called looking for your lost keys at
night, beneath the only streetlight. It's not that you lost them
there, it is simply your only working option. You may appreciate how
poor this strategy actually succeeds in the real world.

Static is not a normal indication of good operation. That much rings
true. However, tuning antennas is improvement by degree, not by leaps
and bounds - unless something very obviously wrong is quite visually
evident with the antenna. You may even have to accept the possibility
that this system never worked very well to begin with.

You say a couple of busses work well, and this in its own right tends
to remove the repeater from the list of problems - but your
description of problems is still slim. You say nothing of terrain,
service area (how many square miles, blocks, or whatever), or pattern
of coverage. Unintelligible is another fuzzy word to describe
communications. Is this because of static? distortion? other noise?
weak signal? Is this static: ignition noise? road noise? power line
noise?

FM communications rarely presents you with noise problems unless your
power level (from the repeater) is seriously low or your receiver is
seriously mistuned, or its antenna situation is seriously mangled
(have you looked?). Receivers don't get mistuned typically, and
antennas are quite robust. You already offer that point to point comm
on ch 2 is a mixed bag. Start by using what field medics call triage.
That is separate the well from the infirmed, and the dead from those
who need help.

In the end, you can spend far more at $15/hr accomplishing nearly no
good results than you would with an hour's time from a good tech.
Have you tried talking to him? I bet no more than 5 minutes of
conversation would reveal much.

An antenna model without a feedline will *force* equal and opposite
currents at the feedpoint - it is always fed through the perfect balun!

Add an un-choked feedline to the model (another thick wire, representing
the coax shield) at either side of the feedpoint, and see where the
current goes now. If you don't use a choke on a real-life antenna,
there's nothing to stop the current going wherever it likes.

Consider that if the velocity of space is slowing down, the
volume of space would necessarily be expanding according to
the theory of relativity and photons would indeed lose energy.
The saddle model of the universe seems most likely to me because
of that slowing down process that will eventually lead to collapse
and another big bang.

I would think a 1KW or greater magnetron run off a non-filtered and particularly dirty, but rectified dc supply (you could even feed a ramp or triangle dc power wave to the magnetron to cause frequency sweep) and into a sloppy waveguide exhibiting multiple resonant frequencies would knock out all cell phone and wireless communications on shf+ freqs for blocks if not miles... you would probably start jamming the cell towers for miles around and have every "pirate transmitter" hunter in America on your tail... in a large city/metro area you would cause havoc to break out--this WOULD BE ONE SERIOUS OFFENSE!!! If caught, you would learn to call prison your home!

And Bruce, in the cell next to you, would fall in love with you!

Not to mention the danger of exposure to the freqs in question--this would be best left alone...

Cebik's plot of currents in the "standard" J-pole shows unequal
currents all the way down to the bottom, and he notes this in his text
and asserts the need for a choke.

He doesn't say whether his models do or do not include a feedline.

>Add an un-choked feedline to the model (another thick wire, representing
>the coax shield) at either side of the feedpoint, and see where the
>current goes now. If you don't use a choke on a real-life antenna,
>there's nothing to stop the current going wherever it likes.

Agreed. The results are likely to be quite variable depending on the
feedline distance to the nearest ground. Seems to me that the worst
case would result from a small integral multiple of 1/2 wavelength, no?

My guess is that in most simple J-pole installations, the feedline
radiation and the resulting disturbance of the antenna's omni pattern
are probably not going to be worth worrying about too much. Nearby
buildings, trees, etc. are likely to result in larger differences
in the far-field pattern than any quirks in the antenna's own pattern.

As an alternative to using a choke on the feedline, what sort of
results might one get with a standard J-pole by using a half-wave
coaxial balun and tapping up a bit further on the elements?

An arrangement of this sort might solve two problems at once. One of
the problems I've noticed with making the usual plumber's-delight
copper J-pole for 440, is that the 50-ohm matching points are down
quite close to the bottom shorting-bar. If one makes attachment
clamps out of copper-pipe support straps (as is suggested in many of
the sets of plans I've seen), and if the J-pole is made from 1/2"
copper pipe with elbow and T fittings, it's difficult or impossible to
achieve a good match - the attachment clamps can't be slid far enough
down on the pipes to reach the match point, before they hit the elbow
fittings.

Using a coaxial 4:1 balun would allow the attachment points to be a
bit further up.

With the proper tools, replacement materials, correct knowledge and a
motivated/productive worker(s) (less than your $15/hour mechanic) - you can
improve the operation of this system.

Did you know that many stereo installation workers (e.g. Best Buy, Fry's
stereo shops) and even some LMR shops make about this same wage range?
It is usually an apprentice or entry level position for LMR shops !

So, how can you make it happen?

Richard gave an excellent FIRST step
> "Start by using what field medics call triage."

My Dad and Elmer's taught me 35 years ago that you need to quickly separate
the "wheat from the chaff".
Some of your "problem radios" in buses may actually be "bad radios" AND "bad
antennas". IF a radio has a shorted coax, the final RF transistors inside
the radio may have been damaged (like running an engine with no "oil
warning" light -- damage is or has occurred and you don't know it !)
There is no easy way that you will know this without diagnostic equipment.

> While the repairs made to the repeater did get channel 1 working again,
> it has a high static level with most but not all busses. A couple of
> busses sound relatively clear, while most others are nearly
> unintelligible.

While a number of problems can cause high static levels -- I would FIRST
suspect a broken shield in the antenna coax -- due to rough "installs and
reinstalls" from buses -- so that ignition noise from the bus engine is
being picked up by the radio.

Now, you still need to have a sit down conversation (for research and
business relationship purposes) with your local LMR. The purpose of this
meeting (about 30 minutes) is to introduce yourself and come away with the
following accomplishments. Something like this:

1. Establish a business relationship with the owner or manager of this business. Who is he/she? How long in business? Did they originally install and design this system for the company?
You just handed him a check for services -- and he/she should be happy to do this.

2. Outline -- at a high level -- your problem, which is:
+ Due to regular replacement of buses, your staff has to remove and install 40 radios very 12 to 24 months.

+ You have recently joined the company and discovered that the knowledge to do this work properly has been lost (due to employee turnover).

+ The company needs to regain sufficient knowledge to perform this work at "odd hours" or on "short notice".

+ You would like a proposal from this LMR company:
Cost to perform this changeout service per bus (at their facility OR at your facility - likely 2 prices here) - and any discounts for guaranteed volume of work (per bus) for a given time period.
(This service should include assurance of both the radio and antenna)

3. Ask the company if they would be willing to have 2 of your staff members "shadow" his install technicians. I know of many LMR that are restricted from doing this by their business insurers (similar restrictions exist for many insurance policies at automotive and truck garages - you may have such a restriction at your own bus garage
Your staff likely knows "buses" better than his LMR techs - and joint knowledge may be required for proper power routing to radio and antenna placement on the bus. No one has mentioned this - but the placement of a UHF antenna on a large bus is a KEY DECISION for proper operation.

AFTER, you get his written or verbal proposal, I would suggest that you propose to your management to try this out on the 2 bus radio installs - for you suspect that there are several issues at work in those instances.

Select the worst 2 bus radios --- preferably to be removed and installed in 2 brand new buses. This is what I refer to as a "BOOT STRAP" upgrade - taking the worst and making it the best.
NEW BUS - GOOD RADIO, POSITIVE Driver comments about these NEW BUSES - immediate quality improvement -- easier to continue program -- you get "buy in".

You will likely find the following reported to you by the LMR company -- as they have the "UHF bus radios" on the bench.

1. Bad coax that needs replacing
2. New whip required for antenna or "recutting"
3. You may require "noise suppression" on the power lead from the battery due to engine noise (e.g. spark plug, ignition system)
4. Damage or failure of the radio -- if you have no maintenance agreement -- this is break fix at a bench rate -- the alternatives are NO RADIO, FIX RADIO or REPLACE RADIO

Lastly, although you are upgrading and changing buses on a regular schedule (and tires) - where is the yearly budget allocation for the communication system? Did you know that if you handle the accounting properly -- you can include these radios in the overall capital depreciation of the buses?
IF you did not know this (kick your accountant in the ass for me) - that is pretty basic.

Hey Al, if I send the antenna back to you, will you refund
my money? What will the bank do with a $00.00 refund?
Your antenna certainly works as advertised, and like the
Zepp after which it was patterned. But I don't know of any
real-world antenna that is immune to common-mode problems.

Cecil:

I should have mentioned the 11th Commandment and saved others...

11) Thou shalt not disagree with God.

... hey, did you bring that bottle of wine with ya, it is hot down here?

Warmest regards,
John

Well, let's see. 1/10 of 360 degrees = 36 degrees.
What am I missing?

Defending your friend even when he is wrong is admirable but
why is your translation better than mine? Incidentally, that was
humor based on my time at Texas A&M during the 1950's. Freshmen
had to admit to upper-classmen that they were lower than the
lowest ... You (and Roy) absolutely hate anyone who disagrees
with you and engage in hazing (ad hominem attacks) to try to chase
such a person away from the newsgroup. Why do you fear the facts?
You two guys consider yourselves to be such omniscient gurus and
never admit a mistake except maybe for an occasional typo.

Einstein is rolling over in his grave laughing at Roy's assertion
that photonic energy can "slosh around" in the transmission line.
Photonic energy always travels at the speed of light obeying the
laws of conservation of energy and momentum. (Shades of the court
that convicted Galileo to house arrest. If you think you are
capable of convicting me to house arrest, come on down to Madison
County, TX and meet all my cousins in law-enforcement. :-)

Yes, he is quite obviously as innocent as OJ... with his money, I think we knew that right off... still, it would interesting hearing how the jury arrived at that conclusion. It is almost like they were angry at the prosecutor and sending him a message with their verdict--as I expected them to find him guilty of at least the misdemeanor of furnishing wine to the kids...

1055. Re: Coax phasing delay

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-13 22:27:58 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <11as23iq4taglc3@corp.supernews.com>
Source record: 75121

It depends.

First, ONLY IF THE TRANSMISSION LINE IS TERMINATED IN ITS CHARACTERISTIC IMPEDANCE: If the coax is 1/10 *electrical* wavelength, the delay is 36 degrees (360 * 1/10). If it's 1/10 *physical* wavelength (that is, the physical length of the line is 1/10 of a free space wavelength), the delay is 36/VF degrees where VF is the velocity factor.

IF THE TRANSMISSION LINE ISN'T TERMINATED IN ITS CHARACTERISTIC IMPEDANCE, the delay of voltage and current won't be the same and, depending on the load impedance, both can be very different from the delay when the line is terminated in its characteristic impedance. The voltage and current delays can be known only if the characteristic impedance of the line, the impedance of the load, and the electrical length of the line are known(*).

(*) Actually, you only need to know the ratio of the load impedance to the line's characteristic impedance and not their actual values.

I guess people are getting sick and tired of your second-rate debating technique, Cecil. I've seen Roy admit to mistakes time and again, while the number of times you've admitted being wrong are essentially zero. If you want to get psychological about it, I think anyone could make

a good case that you're projecting your own failings onto other
people.
Like a few others on this newsgroup, I'm looking forward to
your piece in QEX. I have a theory, that people who develop theories of
energy - in your case, power - and then defend them as strongly and
hysterically, as you do, are closet perpetual motion enthusiasts.
It will be interesting to see whether or not my admittedly
crackpot (but not as crackpot as your ideas) theory is true in
your case.

Hey Al,

Don't let the nay-sayers in this NG bother you, and don't waste
your time arguing with them.

Some of them can't stand the thought that any antenna which differs
from their personal pet(s) might be good. Others can't grasp the
idea that when model predictions and actual results differ, it's the
results that count. Still others can't seem to understand that effects
too small to measure usually do not matter in the real world.

Your antenna is beautifully made, very reasonably priced, and
you are (apparently) making a successful small business with it.
Your customers are delighted, and refer their friends. You are
starting to attract imitators. How many of these accomplishments
can the nay-sayers claim?

Keep up the good work... the XYL and I love our three OSJs!
And they are now pretty much standard in our ARES/RACES
organization. NO complaints heard to date.

73, Ed, W6LOL

<Sniped>
>I don't believe you can totally eliminate all current. There will always be
a small
>amount.

Agreed, but it is small enough I don't think most people could see a
difference in performance if it had a choke or not.
All I am saying, to say the antenna won't work with out a choke is just
wrong.

>I doubt I would change the antenna....Would make it cost more...
>I'd consider a super deluxe version for a higher price, if they wanted
>full 2 section decoupling...:/ And if I went that far, I'd use a dual
>5/8 design to get more gain. You'd be reinventing the isopole...:/
>MK

I have an "Isopole" here in the shop, it works good, maybe one of the
best
5/8 wave antennas I have ever tested. I think it could be built a
little better.
I have seen a lot of them that were broke.
But that is comparing apples to oranges

The OSJ is a simple 1/2 wave antenna that has 0 dBd gain.
No magic.
Again, I just think it is wrong to tell someone the antenna won't work
with out a choke.

I think this guy:
http://www.synchronizeduniverse.com/
and his collegues are about to bring us to a new renaissance of technology...

He is one of the few brave scientists with the cajones to step forward and say there is truth in the enigmas, aberrations and anomalies which have been witnessed for decades now--and ignored...

Undoubtably, if you think you knew the answers--you are going to have to rethink that attitude...

Much of this will cause changes in our "antenna religion" we now practice it today--perhaps even forcing us to construct a "scientific antenna theory" to hold the new redefined theory which is rising on the horizon.

If the ancient Gods of "antenna religion" were upset before--their state is soon to rise to a much greater level of anxiety... soon I expect "antenna zealots" to be running wild in the streets attempting to slay the blasphemous "antenna new agers."

Pays to keep an open mind...

Warmest regards,
John

If the tranmission line between the transmitter and the antenna has a velocity factor greater than unity, then you'll be able to hear yourself before you say it. That could be useful for politicians.

I agree. The question assumes the coax is 1/10 wavelength considering VF. -
so 36 degrees is a slam-dunk.
But 'delay' infers there is another signal to be compared to for the delay.
If you compare the signal on one end of the coax to the signal on the other
end of the coax, then there's your delay.

But on previous threads, I thought you said that speed was not a valid unit
for measure because speed depends on time, which depends on the spin of the
earth on its axis.

Typically biased, Tom. I have admitted I was wrong at a rate of
at least three to one compared to Roy. I feel sorry for you if you
agree with Roy that when a 50 ohm SWR meter reads 4:1, the system
is Z0-matched to 50 ohms. I feel sorry for you if you insist a lumped
circuit analysis is appropriate for a distributed network problem.
I feel sorry for you if you insist that EM waves can exist without
their associated ExH energy. I feel sorry for you if you deny that
interference plays any part in transmission line matching.

How about Roy's assertion that photonic energy "sloshes" back and
forth in a transmission line? I don't recall Einstein ever saying
such was even possible. Do you really believe that photonic energy
"sloshes" back and forth? If so, I've got some "Ocean Front Property
in Arizona" reserved especially for you.

You guys have a good old boys network going here that ignores the
laws of physics and reminds me of the Spanish Inquisition. Sorry,
once in history was once too many.

Nope, your foot cannot move when you are traveling at the
speed of light. Neither can dust. Time stands still so
absolutely nothing happens.

Interesting paper concerning microwave magnetrons at
http://www-personal.engin.umich.edu/~mcjz/papers/neculaes_tps04.pdf

Mention is made of magnetron cavity Qs in excess of 200. The spectral width of such a source, at the 3 dB points, would therefore be about 12 MHz. Not really suitable for CW, but far better than my observations. Comments about poor power supplies are probably correct.

It is interesting to note that the spectral purity of oven magnetrons is of concern with regards to interference to the 2.4 GHz ISM band.

There are techniques for the stabilization of magnetrons when used for Moving Target Indication (MTI) on RADAR systems.

The fact is it is very easy to build a high stability synthesizer -- with spectral widths of the order of 1 or 2 Hz -- at 2.4 GHz. Amplification is another matter, since a 2.4 GHz TWT probably costs around $7,000.

73,

Frank

Vintage Moore. As I said, Cecil, people are finally getting tired
of your silly postings. Now you've been plonked. Next you'll be
replonked, again and again until all your posts go unread.
Maybe you can convince yourself you're an unrecognized genius.
It's always good to have that to fall back on.
73,
Tom Donaly, KA6RUH

Al:

This room is less about antennas than it is about egos, hero worship, and the "good ole boys club."

I have seen egos here large enough to chase all the air from the room--leaves one breathless... a couple of these guys are even "LEGENDS IN THEIR OWN MINDS!", now that's gotta count for something!

Perhaps we will eventually get some 25 to 45 year olds in here and restore some progressive thinking, discussion, debate and argument which civilized men can conduct in productive ways... those who have had their day in the sun (or 15 minutes of fame) will eventually move on.

Right now, there is little point in fighting the "status quo" here--they turn like a pack of wild dogs in attack if even someone poses an original thought, or explores an unconventional path... one poor long tall drink of water from Texas is taking his lickings for this now.

It does have the effect of chasing off fresh new minds which would be of interest to us who would enjoy group participation--rather than a lecture by a dinosaur (and I can say that even being close to "dinosaur age" myself.)

Hang in there OM... if you have measured those swr's and know your product, people will give it a go...

... the construction seems well done and should provide service for many years...

Should be more than satisfactory for someone just wanting to get on the band(s) and not become an antenna guru. Heck, with an L-Match on it a guy might be surprised how wide that bandwidth can become...

Warmest regards,
John

Regardless, the law simply says that he is not guilty of the charges AS PRESENTED. Innocence is a nice thought but not factual. If double jeopardy did not exist his so-called "innocence" might be turned into a guilty verdict. So, once again for the stubborn of thought - he is not innocent. Rather he is NOT GUILTY OF THE CHARGES AS PRESENTED. The jury has already said that they did not believe the PRESENTATION OF THE CHARGES beyond a reasonable doubt.Let his publicity machine proclaim "innocence". They will do a masterful job and lure loving teens into expensive concerts.

In the meantime let his antenna wire wrap around his.......

OK - I stand corrected again.
So movement IS real, but time is not real. Speed depends on movement over a distance in a measured time - so the 'speed of light' does not exist.
But it MUST exist - Einstein squared it.

The movement of light, mainly since it is so stable (however, light may not move at the same speed in all corners of the universe--and under all conditions) can be used to provide the human mind with the belief in the myth of time...

Time to us is the rotation of the earth, measured in 1/24 units of a full revolution, and fractions thereof.

Also, wwv and wwvh use atomic clocks, they count how many atomic particles are lost in decay of radioactive elements to provide the myth of time...

... hourglasses use the rate of sand falling through a narrow opening...

... clocks count the spinning of a gear or the frequency of a quartz vibration...

... time is movement/change... you cannot hold time in a bottle--you CANNOT measure time--you only measure movement...

... formulas which use time in them are just incomplete at the present time, eventually a more accurate formula will be developed in many of these cases...

... those formulas which incorporate the movement of light might be correct... that movement is real at least... (well, I think it is real <grin>)

Warmest regards,
John

I haven't been ignoring this thread, I have been trying to figure out
eznec. I have managed to make it display a dipole and a two element
beam. I'll need to learn the more advanced features.

I'll try what you say If I can understand the program well enough to
do so.

Again, I just think it is wrong to tell someone the antenna won't work
with out a choke.

Well, obviously I've never said that. But I have done many
tests with 1/2 waves with and without decoupling sections.
They were always improved with the extra section.
I just mainly wanted to clarify that no matter how the
antenna is fed, or no matter the SWR, which is totally
irrelevant, you still have to contend with the spillover
currents. The only cure for that is a decoupling section,
choke, or whatever.
As far as I know, the isopole was electrically the best
dual 5/8 ever built as far as decoupling the line. I've
never heard of any competing designs beating it.
The ringo ranger II is slightly inferior.
But the isopole is also pretty ugly...Looks like a missile...
I'm not saying it doesn't work ok now. I'm sure it does.
I'm just saying it would likely work a bit better with it, and
be more stable as far as common mode currents
per users at different sites. I agree. I don't think you
should change it...There are other designs if you want
higher performance..Anyone wanting to further
decouple the line can add their own chokes, etc..
The ringo ranger II was cushcrafts answer to the isopole.
Before that, they sold the ringo ranger. It was basically
fed the same way as the J pole, except using the gamma
loop. Like the version you use, the gamma loop ain't
half bad at decoupling the line in itself. It was fairly usable
as is, and many used it for a few years...Then the isopole
came out, with basically the same dual 5/8 design, but
with decoupling. It just tore the ringo ranger a new one...
Smoked it....Cushcraft knew they had a major problem.
So they designed a decoupling section to add below the
regular ringo ranger. Made a *huge* difference in performance
for most users. I know myself, I tested it with and without the
decoupling section, just out of curiosity. On local repeaters,
the average difference was 3-4 S units, using an icom 22u.
And thats totally reciprical. On VHF/UHF, I've found that
decoupling is generally more important to low angle gain,
that any gains from element lengths, or collinears, etc...
A well decoupled 1/4 wave ground plane can easily match or
beat a poorly decoupled much taller ringo ranger with no section...
Myself....I prefer a small yagi....:/ I have a three el for FM,
vertical...

Smokes any vertical....MK

Don't let the nay-sayers in this NG bother you, and don't waste
your time arguing with them.

At this point, I don't consider my thoughts, arguing....
Just stating the fairly obvious...Don't ignore spillover
currents if you want superior performance from an elevated
vertical on VHF/UHF.

Some of them can't stand the thought that any antenna which differs
from their personal pet(s) might be good.

I could care less...He didn't invent the J pole...

Others can't grasp the
idea that when model predictions and actual results differ, it's the
results that count.

The actual results count...I could care less about the models.
I've tested all this in the real world, with real antennas.

Still others can't seem to understand that effects
too small to measure usually do not matter in the real world.

Total BS in most cases....I seen the lack of decoupling totally
ruin otherwise decent antennas... I've personally tested and
seen easy 3-4 s unit differences in the same exact antenna , with
and without the decoupling section connected.
Decoupling is critical to high performance on VHF/UHF.
All the best designs include it.

Your antenna is beautifully made, very reasonably priced, and
you are (apparently) making a successful small business with it.
Your customers are delighted, and refer their friends.

Yes, I agree. I know many people that use his arrow yagi's
for SAT work...Just because his J pole doesn't have a decoupling
device doesn't mean he doesn't build good antennas...Not that many
people decouple J poles...I've never understood why...But there it
is...

You are
starting to attract imitators.

The J pole has been imitated numerous times....
Or are you talking about arrows?

How many of these accomplishments
can the nay-sayers claim?

Ugh....I'm not in the antenna biz...But If I were....but If I were....
I would decouple *all* my VHF/UHF verticals.
Myself, I doubt I would even sell a J pole...
I'm not particularly fond of the design...
I would sell a super duper isopole II.....
Decoupling out the ying yang...
And yes, I'm sure it would cost more than $39.00...
MK

<Sniped>
>I don't believe you can totally eliminate all current. There will always be a small
>amount.

Agreed, but it is small enough I don't think most people could see a difference in performance if it had a choke or not.
All I am saying, to say the antenna won't work with out a choke is just wrong.

>I doubt I would change the antenna....Would make it cost more...
>I'd consider a super deluxe version for a higher price, if they wanted
>full 2 section decoupling...:/ And if I went that far, I'd use a dual
>5/8 design to get more gain. You'd be reinventing the isopole...:/
>MK

I have an "Isopole" here in the shop, it works good, maybe one of the best
5/8 wave antennas I have ever tested. I think it could be built a little better.
I have seen a lot of them that were broke.
But that is comparing apples to oranges
The OSJ is a simple 1/2 wave antenna that has 0 dBd gain.
No magic.
Again, I just think it is wrong to tell someone the antenna won't work with out a choke.

nm5k:

I agree with you on some you say, and on some of it disagree...

Some, like me, care most about getting something up you can use and/or tinker with... and I work with computer models all day, I like to get my hands dirty...

Others want it to be perfect "on paper"...

This is not a case of one being right over the other--and no matter what their goal--I would like to accept it as a valid goal without question.

It helps to try to formulate answers to help the particular person in question towards obtaining their goals--as opposed to impressing them with ones personal knowledge--well, unless that is what they wish and/or that is acceptable to them.

There are men with good sound knowledge here, I do not question that--just sometimes they could present it in a manner which is more pleasant and tolerant... either way I will accept it, however I think some of the "faint at heart" are chased away...

And in any case, it does not hurt to know the fine details of something--take the balun/choke and feedline currents for example--heck, you can run with the currents... and, if you ever get tired and wonder what it would be like to run without them, doesn't hurt to have gained the knowledge to quickly wind a current balun and chuck it in the line...

Warmest regards,
John

Source record: 75210

what is never GOOD is having another tell one WHAT IS GOOD for
them... if you do that in normal life, expect to get told off as often
as here...

What is good is talking to people that don't
have their heads up their rearend.
All I'm doing is stating fairly simple facts.
If you choose to ignore them, fine with me...
But don't start with your goofball behavior pattern
just because I'm trying to clarify that *no* type of feed on an
elevated vertical is capable of fully decoupling the antenna
on it's own.

I quote from Al's first post....
"One think you may have missed, the original post was about a Arrow
Antenna J-Pole. This is an Open Stub type J-Pole, Not a Closed Stub
type like the copper pipe ones. The OSJ does not need a choke, it does
not have a problem with feedline radiation or a problem with Common
Mode Currents. "

That statement is *false* if you want the best performance.
That type of antenna is most certainly able to suffer from
feedline radiation. Sure, it may be better decoupled from
the line using his method vs another, but that does not deal
with spillover currents. There must be a 2nd decoupling device to
deal with those currents. The antenna does include that as
sold.

If you think I really give a hoot about Arrow antennas, or Al,
or whoever, you are sadly mistaken. He would have never
heard from me if he hadn't said that his J pole can't suffer from
common mode problems.
I'm a dumbass compared to many of these people, and even I
know thats a silly statement to make, unless you like holes in your
toes.
Oh...And I can't ever recall ever being "told off" on any post, on
any NG...I don't have the behavior patterns, hyperactivity, etc,
that you seem to exhibit. So I don't attract the attention that people
like you do. The only people that ever get me going are smartasses.
I have run across 4-5 real® smartasses on my journey through the
internet.
They tried to tell me off, but I quickly showed them that that was an
effort in futility. I'm rated a black belt when it comes to
smartasses.
You wanna be #6 on the list? Go ahead...Make my day....

At this point, I don't consider you a full fledged smartass...
You are like a 9 year old that is hyperactive from gorging on
chocolate, that turned out to actually be coated preluden pills...
So I cut you a bit of slack...So far.....Don't push your luck...

You would have never heard from me, except that your post struck
me as overall BS...As usual....
Note...

This room is less about antennas than it is about egos, hero worship,
and the "good ole boys club."

Only people that are defensive, or are trying to cover something up,
or trying to claim some silly nonsense would feel this way.
All people have ego's to varying degrees.
Best to ignore....
I would never worship a man.
I don't belong to any clubs, but I reckon if I did, I would
prefer a bunch of good ole boys, over a bunch of anal
retentive "girly men" who constantly feel victimized
by the world in general...
MK

> . . .
> Again, I just think it is wrong to tell someone the antenna won't work
> with out a choke.
>
> 73 Al Lowe N0IMW

I agree entirely. In fact, I think it's wrong to tell someone that an antenna won't "work", regardless of how good or bad it is. The only exception I'd make is if the person has some very well-defined criteria about what constitutes "working" and what doesn't, but very few people do. Most hams want to talk to someone, and most antennas will allow them to do that, with a minimum of fuss, optimizing, or knowledge -- that is, most antennas "work". Once that basic need is met, durability, construction quality, and customer support rightfully become the most important items in choosing a commercial antenna.

Just about any antenna can be made to work better in a technical sense (for example, higher gain in some direction). But a technical improvement that doesn't cause any improvement in operational use isn't an improvement at all. If the repeater you want to talk to is full quieting in both directions, no technical improvement in the antenna will improve your ability to communicate, so there's no point in putting forth the effort. Who cares if your car can go 120 or 140 MPH if you never drive it over 70? [Considering the giant immaculate scratch-free four-wheel drive vehicles overpopulating the suburban roads, I'm afraid that's not a good example.]

On the other hand, if you're trying to operate under marginal conditions, even a small technical improvement in the antenna performance translates to an enhanced ability to communicate. That's where it pays to know something about how antennas work, and where it can be worth the time and trouble to make the improvements. I have to say, though, it's sometimes discouraging when suggestions about how an antenna can be improved are interpreted as saying an antenna "doesn't work" without the improvements. It's awfully hard to penetrate through the binary way of thinking most people seem to be stuck with.

It's really a shame that some manufacturers of good, serviceable, durable antennas feel they have to create some special and magical quality to convince people to buy their products. But I guess that's the reality of the marketplace. Works for cars, works for medicine, must work for antennas too.

Roy Lewallen, W7EL

>You two guys consider yourselves to be such omniscient gurus and
>never admit a mistake except maybe for an occasional typo.

I don't hate you in the slightest, Cecil. I just hate sloppy thinking.

This is not an ego thing. It's all about defending the bedrock of basic
scientific principles and logic. If Roy or I appear rigid and
unyielding, that's because neither of us is prepared to give way if it
means breaking those basic principles.

THE most basic principle of physical science is that every bit of true
knowledge is a piece of a huge jigsaw puzzle that fits together with
everything else that's true. If it doesn't fit in with every other
piece, then it ain't true.

The absolute fascination of science - and science-based engineering - is in understanding *how* they fit... and very occasionally, finding a few new small pieces.

Antennas and transmission lines are bloody difficult, and complex in every sense, so it's sometimes hard to see how the pieces fit. But that makes it MORE important to hold fast to the underlying knowledge that they do fit... if we could but figure out how.

The wrong way is to say: "This big puzzle is too hard, so I'll make up my own little patch over here, and who cares if it doesn't fit?" Well I care! I also care if other people are being led astray by the loudest voice or the most prolific poster.

But that principle is a hard taskmaster. It means that every notion has to be tested to see if it fits. It means being prepared to throw away a dozen pet theories before lunchtime, if they fail to fit into that big jigsaw puzzle. It means that getting it right is vastly more important than "winning" an argument, or being the last man still posting when a thread dies out.

Roy and I agree on a lot of things - so much so, it must often seem like collusion. But it isn't - it's just another result of those basic underlying principles. They are exactly the same in Oxford as in Oregon, so if each of us gets it right independently, then we're inevitably led to the same conclusions.

Anybody can make mistakes; and if that happens, Roy has often said he wants to be corrected. So do I. If he and I don't agree on something, the most important thing to either of us is to understand why. Give either of us a convincing argument - namely an argument that fits in correctly with the rest of scientific knowledge - then we'll gladly agree and be happier for it.

In contrast, I have lots of disagreements with Reg! But they are all about judgement calls, such as the best methods to use, or what other people do or don't need to be told. We approach those topics very differently, and may never agree; but I don't recall ever having fundamentally disagreed with Reg on basic principles, and don't ever expect that to happen.

And finally: yes, I have met Roy Lewallen. When my vacation flight in 2000 passed through Portland, we naturally made it our business to take a look at each other! What you see here is the same guy when you meet him. I am pleased to count him as a friend; but more important than friendship is his uncompromising intellectual honesty about trying to deal only in true facts.

Well, there it is. Cecil, if you still see any of this as an ego thing, or merely "defending a friend"... then you haven't understood a single word.

As an alternative to using a choke on the feedline, what sort of
results might one get with a standard J-pole by using a half-wave
coaxial balun and tapping up a bit further on the elements?

Still don't think that would clean up spillover currents...
If I were to use a J pole, and wanted decoupling, I would
add a 1/4 wave coax section below the feed, and then
have a set of radials at that point. They can be grounded
to the mast, or left free, as long as they are connected to
the shield. The 1/4 wave of coax is physical length, not
electrical. But I've found in testing, it's not all that critical.
Of course, he wouldn't be able to claim "no radials" at that
point, but it would be pretty well decoupled. This is the same
basic design cushcraft used with the ringo ranger. In that case,
the coax length was 50 inches long, to a set of 20 inch radials.
They used the longer length due to the dual 5/8 design.
They actually seem to claim that 50 inches of coax as a 3rd
radiating element, but I don't quite see it that way. If that were
truly the case, it would beat the isopole.
The comparison between the isopole and the ringo ranger 2
show how important decoupling is. They are both appx dual
5/8 designs. No real difference in element length.
The isopoles improved decoupling is what make it the winner
when you compare the two head to head.
A sleeve would also be easy to use with a J pole...
Actually, I sort of prefer the center fed 1/2 wave "sleeve"
dipole vertical, with a 2nd lower decoupling sleeve, over the
usual J pole design. MK

Ian, not wishing to be classed amongst the old wives you have very carefully avoided talking about "power radiated from feedlines". You have shifted to using clamp-on ammeters.

But people who DO discuss things in such terms are unable to justify the use of chokes by quantifying the power actually radiated and setting limits on what power level is acceptable or is not acceptable. If they can't measure or calculate the power level then they know nothing about what they are are talking.

Refer to what Lord Kelvin said about measurements.

Can you suggest an acceptable level of amps as measured on a clamp-on ammeter?

If they did, the configuration of the feedline would become another
important variable which he couldn't fail to mention. Also the drawings
show no feedline.

>case would result from a small integral multiple of 1/2 wavelength, no?
>
That's right. At the point where the coax shield connects to the
antenna, the current will divide three ways, between the antenna, the
inside of the shield, and the outside of the shield. The split will
depend on the ratio of the impedances in each of those three directions.

If the impedance for current flowing down the outside of the shield is
low (which any multiple of 1/2 wavelength grounded at the bottom will
achieve) then away the current will go - there's nothing to stop it.

A feedline choke creates a high impedance against current flow down the
outside, so the current from the inside of the shield flows almost
exclusively into the antenna.

Even if you choke a J-pole at the feedpoint, there will also be induced currents further down the feedline because the antenna and the feedline are usually installed in a straight line. But that doesn't override the need to choke the feedline at the most obvious place.

>My guess is that in most simple J-pole installations, the feedline
>radiation and the resulting disturbance of the antenna's omni pattern
>are probably not going to be worth worrying about too much. Nearby
>buildings, trees, etc. are likely to result in larger differences
>in the far-field pattern than any quirks in the antenna's own pattern.
>
Most people using J-poles won't worry, that is true... but that's mostly because J-poles are used in relatively undemanding applications where you either hit the repeater or packet node, or you don't.

In defence of Al, if the J-pole is mounted directly on a car roof, then there's no point in attempting to choke the feedpoint. But if it's mounted on a mast, the mast and feedline will radiate. How much will depend on the exact installation, and is pretty well unknown unless you can measure the actual RF currents.

>As an alternative to using a choke on the feedline, what sort of
>results might one get with a standard J-pole by using a half-wave
>coaxial balun and tapping up a bit further on the elements?
>
That is a workable feed method, but the half-wave balun is a voltage balun. The antenna is asymmetrical, so the balun is acting as center-tapped voltage source which is trying to push equal currents into the unequal impedances on either side of the feedpoint. That will never quite succeed, so there will always be some out-of-balance current left over.

Like all voltage baluns, the half-wave coax type doesn't do anything directly to *prevent* the out-of-balance current from flowing away on the outside of the feedline. On the contrary, there is a hard-wired connection that will *allow* such currents to flow.

That's not really quite true. Can you or anyone else tell how many watts is radiated from each element of a Yagi? How? Then how do you know which elements are important an which are not?

>ammeter?

No. Reg knows perfectly well that the RF current is only one part of a
much bigger picture.

An acceptable level is one that:

1. Does NOT make the microphone bite your lips (or does not leave
lasting scars :-)

2. Does NOT cause your transmitter to act up because there's too much RF
current flowing through your station, trying to find "ground"

3. Does NOT cause RFI to your family and neighbours

4. Does NOT cause unpredictable changes in transmitter loading

5. Does NOT lead to unacceptable pickup of interference when you're
trying to receive.

So that "acceptable level" depends entirely on each individual's
particular station layout, how they operate, where they live, what kinds
of consumer electronics the family and neighbours use, how they are
installed... and how much that individual ham cares about getting along
with the family and the neighbours.

Every case is totally individual. That is why every individual needs to
do his own thinking and make his own decisions.

The only "old wives' tale" is that somebody else can do it for you, or
tell you from 5000 miles away what does or doesn't matter.

You don't actually need to measure amps in order to make those decisions. Basically it's all about simple practical things like the list above.

Where the RF current meter really helps is if you decide you do have an RFI problem. Then it lets you *see* how well you're managing to fix it. Too much of RFI investigation work is like groping in the dark. The RF current meter is like taking a blindfold off.

Neither you, I or anybody else knows. But, as usual, you have put
your finger on the source of the trouble. It's a descriptive language
problem.

To speak in terms which most people understand, when Cecil acquired
his burn the injury was just as likely to come from the antenna as it
was from the feedline.
Actually, it came from the PA via the tuner.

It is not entirely unrelated to the confusion about standing waves
caused by referring to the so-called SWR meter as an SWR meter, when
it doesn't do anything of the sort and, in any case, there is no line
in a position on which SWR can be measured.

I apologize for exaggerating yesterday's situation through
hyperbole, a character flaw in my tongue-in-cheek dark humor.
"Shirley, you jest" is a hint.

> Well, there it is. Cecil, if you still see any of this as an ego thing,
> or merely "defending a friend"... then you haven't understood a single
> word.

And here's your chance to back up those elegant words.
Here's a repeat of Roy's example:

100v
source--x----1/2WL 50 ohm feedline----+--200 ohm load
50 ohm

A 50 ohm SWR meter measures 4:1 at point 'x'. Roy says:
"But there's a Z0 match at the source in my example."
What do you say?

Don Gillies wrote:
"---none of these has explained where the two points are that the voltage is being measured between."

Kraus calls the potentials near and far from antennas "retarded potentials", involving t-r/c, where t is time, r is distance from the origin, and c is the speed of light in free space.

On the conductor itself, the origin would seem logical as a reference point for antenna voltage. Antennas are often considered as extensions of the feedline,

Feedpoint rms voltage is simply the potential between the wires at that point. Instantaneous volts depend on phase along the antenna, impedance, reflection, mutual coupling, radiation, and loss.

Best regards, Richard Harrison, KB5WZI

Hi Guys, Just been to the web site for the info on the Solarcon A-99.

What I now need to know is how to remove the internals intact. Question is; how is the wire at the radiating end terminated in the metal housing, is it soldered in or machined in? at the centre or the side? Obviously the short length of coax is soldered in at the PL239 end. All the joints in the first section are loose now, so I just need to remove the internals to see what's happening. I don't have continuity here but surely I should, even if shunt fed!! I don't want to pull too hard in case I end up damaging the coils Etc. I just fancy playing on 10 or 15/P if it tunes up decent enough and the bands open. Any Idea's. Cheers and TIA Dave

And the "RF current meter" doesn't have to be expensive or
complicated. A before/after relative current value may be
all one needs. I use a toroid with ten turns feeding a
1N34A curcuit and a DC voltmeter with very short leads. It
was "calibrated" using forward current into a 50 ohm load.

Simple measurements like this are covered in, "Baluns,
What They Do And How They Do It", by Roy, W7EL, in the
ARRL Antenna Compendium, Vol 1, article available at:

:-) You need a virtual ground to obtain those voltages. Actually,
they are deduced to exist because P=ExH and we can measure the
antenna current associated with a certain power level. Some purists
say that if a voltage cannot be measured, it doesn't exist. Some
detectives deduce its existence based on the laws of physics.

Dear Dave also in MI:
The bracket (at the bottom of the antenna) appears to include three
attachments to the antenna. The picture seems to indicate that the highest
attachment is insulated from the antenna proper.
If you know, are either of the other two attachments insulated?

It is difficult to believe that a passive antenna with no moving parts
is able to present an impedance of about 50 ohms over three octaves without
using resistance to swamp the reactance.

It will be interesting to learn what is inside.

what is never GOOD is having another tell one WHAT IS GOOD for them... if you do that in normal life, expect to get told off as often as here...

What is good is talking to people that don't
have their heads up their rearend.
All I'm doing is stating fairly simple facts.
If you choose to ignore them, fine with me...
But don't start with your goofball behavior pattern
just because I'm trying to clarify that *no* type of feed on an
elevated vertical is capable of fully decoupling the antenna
on it's own.

I quote from Al's first post....
"One think you may have missed, the original post was about a Arrow Antenna J-Pole. This is an Open Stub type J-Pole, Not a Closed Stub type like the copper pipe ones. The OSJ does not need a choke, it does not have a problem with feedline radiation or a problem with Common Mode Currents. "

That statement is *false* if you want the best performance.
That type of antenna is most certainly able to suffer from
feedline radiation. Sure, it may be better decoupled from
the line using his method vs another, but that does not deal
with spillover currents. There must be a 2nd decoupling device to
deal with those currents. The antenna does include that as
sold.

If you think I really give a hoot about Arrow antennas, or Al,
or whoever, you are sadly mistaken. He would have never
heard from me if he hadn't said that his J pole can't suffer from

common mode problems.
I'm a dumbass compared to many of these people, and even I
know thats a silly statement to make, unless you like holes in your
toes.
Oh...And I can't ever recall ever being "told off" on any post, on
any NG...I don't have the behavior patterns, hyperactivity, etc,
that you seem to exhibit. So I don't attract the attention that people
like you do. The only people that ever get me going are smartasses.
I have run across 4-5 real smartasses on my journey through the
internet.
They tried to tell me off, but I quickly showed them that that was an
effort in futility. I'm rated a black belt when it comes to
smartasses.
You wanna be #6 on the list? Go ahead...Make my day....
At this point, I don't consider you a full fledged smartass...
You are like a 9 year old that is hyperactive from gorging on
chocolate, that turned out to actually be coated preluden pills...
So I cut you a bit of slack...So far.....Don't push your luck...

You would have never heard from me, except that your post struck
me as overall BS...As usual....
Note...

This room is less about antennas than it is about egos, hero worship,
and the "good ole boys club."

Only people that are defensive, or are trying to cover something up,
or trying to claim some silly nonsense would feel this way.
All people have ego's to varying degrees.
Best to ignore....
I would never worship a man.
I don't belong to any clubs, but I reckon if I did, I would
prefer a bunch of good ole boys, over a bunch of anal
retentive "girly men" who constantly feel victimized
by the world in general...

I am not sure what I just did or saw. I had several colored graphs charted and one gray. The gray didn't seem to move around, but the colored ones sure did. I am afraid I didn't see what you were trying to show me. I believe the colors were the different feed lines, capacitors, etc used in the feedline shown. I tried removing them and only leaving the feedline I chose to use. I don't know if I did something wrong or not, but the gray line appeared to be the antenna and it never appeared to move. The feedline markers moved radically.

I haven't thought a lot about the losses in ladder-type feedline, but I do understand how the losses in coax can reduce High SWR by reducing both the outgoing and incoming reflected signals in the coax. This may make the antenna desirable to the rig, but it doesn't do any good for the operator who is trying to reach or copy that weak signal. It may well be that the Twin-lead has the same effect. I often read that one of the advantages of the twin-lead is that it can handle higher SWR without the higher losses of coax.

I seem to have been seeing a lot about the technology of the twin-lead tuning technology, but then I can't be sure it wasn't from the same people here on this forum. I'll continue to look into it to see what I might learn.

I was able to get past whatever block I had on learning to use EZNEC, so at least some good came from this discussion. Hopefully, I'll learn more and can model this antenna and others I read about.

Thanks very much for taking the time to address this with me.

This is interesting. I remember reading where the G5RV originated as
a gain dipole for 20 meters. I hadn't looked at it as a 1.5wl dipole.
I have always used 1.5wl dipoles for 15 (40 meters) and had low SWR on
the 15 meter band without a matching network. Am i missing something
or is the coax stealing enough power to reduce the SWR?

I'm curious what antenna books those might be. I've seen plenty of books that show current distributions on conductors in an antenna, and plenty that show electric and magnetic field strengths, but darned few that show "voltage distributions along..." antennas.

It makes plenty of sense to talk about electric field strengths, and if you know them, you can calculate the potential between any two points you wish _when_measured_along_a_particular_path_. But the potential ("voltage") between two points in general depends on the path along which you measure it. In particular, if you're in the presence of a time-varying magnetic field (which would be the case around an antenna), the potential depends strongly on the path you take.

Cheers,
Tom

I don't know of any actual USA law that states a citizen is
presumed guilty until proven innocent.

Legally, innocence must be presumed until guilt is proven
in order to avoid violation of due process and civil rights.
If the verdict is "not guilty" the presumption of innocence
legally continues (at least until the civil trial).

I tried it again and got the picture. It appears that the 450 ohm
twin lead sections can match any impedance between 20 and 100 ohms
given the proper length.

> or is the coax stealing enough power to reduce the SWR?

Bingo! Your 15m SWR at the 40m dipole feedpoint is probably
above 2:1. Feedline losses both ways probably reduce it to
a value tolerated by your transmitter. If you replace the
coax with an integer multiple of 15m halfwavelengths of
ladder-line to reduce losses, your transmitter may object.

I have inadvertently stepped upon an unpublished article with
my posting. I apologize and will bow out.

Ok, just to reiterate so I know I understand (and you can see if I
don't), If I feed a 20 meter dipole cut for my favorite frequency, I
can feed the radio with exactly 1/2 wave of 450 ohm feedline and it
will match the radio? Of course, coax will make a better match (with
less loss?)

Now, if I understand, the principle of the 130 foot dipole matching
the rig is based on the length of 450 ohm twin-lead. The twin lead is
always 1/2 WL long. The coax and rig are 50 ohms, but according to
the smith chart, the impedance of the various frequencies range from
20 to 100 ohms. This would make me wonder why I don't get the same
impedances at my rig, or at least at my feed point of 50 ohm coax.

Thanks

> someone make a type-O?

Well, I made an English language blunder as I was editing my posting.
I should have dropped the <which> above. The first piece of matching
section, which can be any length less than 1/2WL, brings the impedance
looking into it to a purely resistive value, i.e. a resonant value,
i.e. a current maximum point. So the first section of matching is the
most important. After that, any Z0 could be used, but *only on that
particular band*. That last *constraint* may be what you are missing
(if you are missing anything at all). I am not aware of any phase
difference between Fred and me.

Not only them, but *any* impedance that causes a 450 ohm
SWR between 4.5:1 and 18:1. That's an infinite number of
impedances (every impedance within the green area) and includes
virtually all the actual impedances encountered when the dipole
is 1/2WL on the lowest frequency of operation. For instance,
the feedpoint impedance of an 80m dipole usually falls into this
green range when used on 40m (and any other HF band) even though
the feedpoint impedance might be 5000 ohms on 40m.

Actually, any integer multiple of 1/2 wavelengths will work

> Of course, coax will make a better match (with
> less loss?)

Amazingly, not necessarily true. Better match? Yes. Less loss?
Not necessarily. Ladder-line with an SWR of 9:1 may actually
have less loss than coax with an SWR of 1:1.

Depends upon the type of coax and the type of ladder-line.

For instance, at 10 MHz, RG174 has a matched line loss of 4 dB
per 100 ft. while 600 ohm open-wire line has a matched line loss
of about 0.075 dB, so small I have trouble reading it on the chart.
Even adding the additional losses due to SWR, the open-wire line
is far, far below the RG174 matched line losses.

> Now, if I understand, the principle of the 130 foot dipole matching
> the rig is based on the length of 450 ohm twin-lead. The twin lead is
> always 1/2 WL long.

Nope. The twin lead is whatever length it takes to resonate
the antenna system plus an integer multiple of 1/2WL. Correct
this concept first before drawing additional conclusions.

Bullshit, a 2.4 Ghz Magnitron would NOT cause any problems for any 800
Mhz or even any 1.8 Ghz cellphone system no matter how bad the
powersupply was filtered. This just doesn't COMPUTE, even in another
world, lifetime, or dimension.

Hey, can someone take the time to do a brief critique of said article?
It might be good to for interested parties to verify their knowledge.

For example, I note:

- The notion that "CB antennas" require a ground plane. My
understanding is that some antenna designs include one or more
counterpoise elements, but that this is different than a ground plane.

- Suggesting that the ground plane is necessary to pick up ground waves.

- Suggesting the ground plane is part of the feedline. If the
groundplane is a counterpoise (as suggested in the first paragraph) why
is the feedline part of the antenna? Is this some sort of special
feedline they are referring to?

- Frequency changes due to changes in the electrical length of the
feedline. Again, unless the feedline really is part of the antenna,
isn't it the idea to have a theoretical perfect feedline can be nearly
any length? That is, from the point of view of the radio equipment, the
feedline has infinite impedance? (I'm fuzzy on this one, so remind me
gently if I'm misleading myself.)

- The discussion of SWR is so wrong it has caused me to forget what it
really is. Sorry.

- The section on tuning somehow conflates the location of the antenna
with it's electrical length.

I invite everyone to set me straight, and in the process offer a good rebuttal of this article.

Homo sapiens have many flaws. Just look at this newsgroup. :-)
Makes me glad that I was an alien life-form left on my
Southern Baptist parent's door step after being impregnated
with all the wisdom of that ancient alien race.

I find it interesting as it has always been flat. Even better on 15
than 40 most of the time. 2:1 isn't terribly bad, most transmitters
allow it, or close to it before reducing power. What is the impedance
of that?

actually I'll try it on eznec, that's one antenna I can model.

Thanks for the comments.

what's the unpublished article? the G5RV? I don't remember where I
have read it, but then as we have seen here many times, not everything
one reads on the internet (or in the newspaper, for that matter) is
accurate.

DOn't shy away. If you know differently, i am open to hearing it.

I think I meant a 1/2 wl interval, but apparently that is wrong too.

If I have an antenna at impedance A, I would first run a length of 450
ohm twin lead for X length which will create the matching impedance
and then any integer multiple of a half wave after that.

A and X being unknown.

Yes. I was in Scotland a week ago and someone told me that there, besides guilty or not guilty, the Scots have a third verdict available. It is "Guilt not proven". In this verdict the person charged is not exonorated but is released. This "guil not prioven" verdict is said to be the origin of the term "Scot free".

0% for logic

F-

Everyone? You quote me above and you ARE responding to the last in a
chain of responses that annihilated your challenge.

You were off by at least a factor of 10 and your material was grossly
inaccurate - it was that easy to prove you wrong. Those details, have
already been examined and their repetition will change nothing.

Bob:

If you don't welcome men/women back into society after they have either run the gauntlet or paid their debt to society--then all you accomplish is creating a whole subset of society which poses great danger when held as "less than acceptable"--indeed, if not careful we can create the monster we fear most.

This is how our ancestors came to overthrow such a kings strangle hold and found this country on principals meant to stop that from ever occurring again--or demand those so oppressed to rise up and throw off such chains once again... it is all recorded in our history...

I think those men who suffered greatly from unfair treatment, indebted servitude, debtors prisons and virtual slavery had it correct--the principals they put forth are as valid today as they were when first stated and put forth...

Still, Michael Jackson would never be left in the presence of my children without me being present... (of course, now all my children are grown) and I would be apprehensive about having him for a neighbor so would set aside a place for him to reside--too bad there are no islands left to exile his type too--perhaps a plea bargain could have been set up with him and he would have gone there willingly...

Warmest regards,
John

1169. 3/2 WL antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-14 21:28:30 UTC
From: Buck <iam@this.site>
Message-ID: <c4iua1llv8be8bptmhq89s4u8ti01pdm6r@4ax.com>
Source record: 74885

An earlier discussion brought to mind the question of the 3/2 wl antennas such as using a 40 meter dipole to operate on 15 meters. I just modeled one using the following stats:

1 wire, 66 feet high, 68.8286 feet long. I then pulled an SWR reading from it from 3.5 to 30 MHz using .1 increments. The result was, of course, two dips, one at 7.0 MHz and one at 21.1. By playing with the alternative impedance, I found that 94 ohms matched both frequencies at about 1.15:1.

Here are some observations about it.

at 7.0 MHz, the shows:

50 ohms -- 1.65:1
72 ohms -- 1.14:1
75 ohms -- 1.09:1
94 ohms -- 1.14:1

at 21.1 MHz, I get the following:
50 ohms -- 2.16:1
72 ohms -- 1.5:1
75 ohms -- 1.44:1
94 ohms -- 1.15:1

The above are the lowest SWR readings (which is why 21.1 instead of 21 MHz)

so, how does one make a 94 ohm match?

I guess you're looking at the Smith chart in XLZIZL. What you are seeing is correct. The gray trace is the load impedance and absent changes in the antenna it will be fixed. If you look right to the legend you will see what each of the colors represents.

So if you've modeled something in EZNEC and read the resulting data file into ZLZIZL.xls and did a "Refresh and show Smith chart" you will see the data plotted as the "Load"

Let's do a little (bit long) experiment that will clarify this (I hope) and also demonstrate some of what happens in a matching network.

1. Open EZNEC and open the file "BYdipole.ez".

2. Go to "Setups" (at the top of the window) and select "Frequency Sweep."

3. When the pane opens, select "On" and type in 14.35 for the "Stop Frequency" and .05 for the "Frequency Step."

4. Under output. check the box "Microsmith Files" and for file name type "g5rv" and hit Ok.

5. Go to the "Wires" menu and change the Y value for End 1 to -51. Change the Y value for End 2 to 51.

6. Do a "Save As" and type "g5rv".

7. Perform a Freq Swp. (Bottom left button).

8. Open XLZIZL, clear any old data or networks and read the g5rv.gam file.

9. Press "Refresh and show Smith chart."

10. The gray trace is the plotted impedance of the feedpoint of the 102' dipole over the 20-meter band.

11. Now at this point Varney (G5RV) recommended a "matching section" of 34' of open wire line, followed by a run of 72 ohm line to the shack. (If you want to see how bad this idea was, you can experiment with adding the lines in the Network dialog)

12. We are going to do it the "modern" way, by using ladderline and a tuner.

13. In the Network definition dialog, select element position 5 and set the type to "Transmission Line", select "Wireman 554" and set the length to 50'. Set the element and close the pane.

14. Press the "Refresh and show Smith chart." The red trace shows the impedance at the input end of the 50' transmission line. Since the desired target is the center of the chart, we can seen that this was a negative "improvement."

Note: I didn't contrive this feeder length, it was just a round number that seemed like an average situational value that follows the "conventional wisdom" that says, "Use a length long enough to reach from the antenna to the rig."

15. This is what we're stuck with if we decide to use ladderline and a tuner, so let's muddle on.

16. In the ZIZL worksheet at row 38 there are some boxes for Component Q. Enter 500 for Qu(C), 250 for Qu(L) and 14 for Q ref freq.

17. Now let's explore a slick feature of this program and design a matching network. Highlight the cells F106 and F107.

18. Look at cell I43 and press "Copy Selected R,X to T-Pi-L".

19. Focus will transfer to the T-Pi-L worksheet and a query window may open asking whether you want to copy the Q values from the ZIZL sheet. Answer Yes. You will no doubt get a second advisory pane that says that frequencies differ. Answer "Ok". Cell H10 will be selected. Type 14.2 into it and press Enter or Tab to input the data.

20. We are now presented with four built-in matching network solutions. The most used topography for commercial tuners these days is the "High Pass T." (Option 1) So we will use it. You can press "Schematic" and see the configuration. Press the "Copy to FT/Solver" button. (Cell B24)

21. The last action took the precalculated values and moved them to the Fine Tune / Solver Area. For now, we won't explore the attributes of this feature. Press the "Copy to ZIZL 1-3" button. (Cell K26)

22. Focus will return to the ZIZL sheet and a query pane will open. Answer "No." If you look at the network definition table area you can

note that there are now three components in addition to the transmission line in evidence.

23. Press "Refresh and show Smith chart."

24. Focus returns to the Smith chart where a wealth of information is presented. In the upper right corner there is a box that shows exactly what the feed system consists of. The "Plot Segments" box shows the legend for each trace and what the effect of each network component is. The informational box to the left will show the parameters of any data point on any trace by just double clicking the point.

Of course, the trace for Plot Segment 1, the input series C, is what we are after. All but the 14.0 MHz point fall inside a 2:1 SWR circle. Let's see if we can fix that.

25. Press the "Tune / Set" button (lower right corner). Long years of experience tell me to tune the input capacitor first, so that's what we'll do, but this may not always be the case. In the pane that opens, select, "1:Series C", which if all of the calculations are the same, should equal 51.2 pF. Mouse down a bit and find the +-1% option and select it. We are going to "tune" the input capacitor in 1% steps. Click the "Increase" up-arrow three times. Voila! The SWR is less than 2:1 over the whole 20-meter band with one set of adjustments. With each click you could see the action of "tuning" this component. Note that none of the other traces moved at all. All we changed was the match between the input and the junction of the input C and the shunt L. The match from the junction to the antenna was unaffected.

Because this is getting a bit long-winded and off-topic, I'm going to stop here and pick this up in a new thread.

lol, no, I have 4 CB frequencies programmed into my 706, Channels 9,
18, 19, and 20. I have them all on a split with the transmit side on
2 meters simplex., as I do with the wx channels and other frequencies
I don't wish to transmit on.

I figure that if I can't get help on 2 meters, HF and a cell phone, I
would be better off calling on CB than on the local sheriffs's
frequencies :). I really don't hear anything there worth listening
too unless I am away and caught in highway traffic. The CBers will
discuss the traffic and how to get around it most of the time.

I keep FRS radios with me when traveling with non-hams in convoy.

Most of the time I am mobile, I am on 14.336 aggravating KZ2P/N2JG.

1. A 2:1 transformer.
2. An LC network. I think at least three components would be necessary for matching at both frequencies, and an exact match would probably require four.
3. A number of different schemes using transmission line stubs.
4. Don't bother. There's nothing wrong with a 2:1 SWR. Feedline loss will reduce it further.

A couple of other notes:

I often use a 40 meter dipole for 15 meters on Field Day. I put a small inductor at the feedpoint to bring the resonance down to the bottom end of 15; it doesn't have much effect at 7 MHz. (If it did, I could get resonance on both bands by alternately adjusting the antenna length and inductor value.)

You can make a nice bidirectional pattern with some gain in two specific directions on 15 by bending the wires toward each other by 30 degrees to make a horizontal vee with 120 degree included angle. This only has a minor effect on the pattern on 40 meters.

I am not in a position to argue with either side on the issue. I am
just doing my best to learn. Here is one lesson I learned in 25 years
of ham radio, Either there is sufficient propagation for your station
or there is not. Without propagation, a kw amp in a 12 element beam
will not get you across the ocean, and if there is sufficient
propagation, one can make a contact with a dummy load (I saw this
demonstrated once on 75 meters).

Probably the things I remember most about antennas is what I learned
from the two Jims of Taylor Radio, a local antenna MFG company at the
time. "More technological advancements have been made in marketing
departments than in Research and Development."

I realize that there are several here who actively disagree and
discuss their disagreements with each other. I haven't seen any, so
far, that are all BS and have no knowledge to offer. I don't
criticize anyone, but I will ask, suggest, and offer opinions that I
hope will be either corrected or supported appropriately.

I have used experimental antennas that theoretically won't 'work' and
made contacts. One was a roll of 500 foot of wire. I unrolled an
estimated 1/4 wave of wire for 80 meters, on the first try it was
1.5:1 or less and I used it to check into the GA SSB net. I had a
weak signal, but it worked. I also hung an inverted V with a random
length of wire from each side (I don't remember the length, but they
were both the same length.) I connected one side of the feedline and
dipole to the left side of a 100ohm resistor and the other side of the
feedline and dipole to the other side of the resistor. My theory was
that the antenna would be a parallel circuit leaving the impedance
below 100 ohms. I don't know if my theory worked, but I did make
contacts. When I took down the antenna and replaced it with a shorter
dipole, I had a much better receiver than I had with the resistor.

I am always looking for that 'best' all-band hf antenna so I don't have to change or tune, etc. One day I'll either find it or die trying. Until then, I plan to enjoy learning more about antennas and experimenting with them.

Hi Don, If one is making a voltage reading, it is between a
reference node, 0.0 volts and a point which is higher or lower in
potential. The voltage distribution on the antennas you saw are
probably with respect to earth or the rest of the universe if you are
in space. This is the reference for the voltage along the antenna.
Volts and current on an antenna are periodic if the antenna is
radiating continously, and you can measure potential difference between
different points along the antenna. I don't think this is what the
diagrams you saw refer, it is with respect to earth, or ground.

You might try this, connect a 50 Ohm feedline to the antenna through an electrical 1/4 wave section of 75 Ohm coax. That should help the SWR on 21, without much effect on 7.

BTW, Roy mentioned bending the elements to form a V. That is what is done on some VHF TV antennas. They work on fundamental mode on channels 2 -6 and 3/2

mode on channels 7 - 13. If you didn't bend the elements, channels 7 - 13 would not come in from the same direction as 2 - 6.

Yagi antennas for frequencies this high are ridiculously compact and easy to build! A full wave is only in the 33 CM area, so a "long" Yagi with 6 or 7 elements would look like a yardstick with 5 inch wires bristling from it. If you only need to send signal in a particular direction, this is the way to go-and reduces the chance of unwanted "listeners" in another direction.

If you need omnidirectional gain, stacked turnstiles floor to ceiling , looking like a pole lamp brisling with 5" crosses, would do it, yielding maybe 9dB or so of gain by flattening out the pattern. Multiple half waves in phase (vertical with 1/2 wave phaseing sections) will do it with vertical polarization. In stacking anything, you get about 3dB gain for each doubling of the number of elements.

Shit, hams on 1215 MHZ and 1KW amps are communicating by bouncing signals off the MOON, with antennas yielding 30dB plus gain being reasonable in size due to short UHF wavelengths.

Me too.

When I was 16, and a newly minted Conditional class, my BC-342 receiver broke (I still have it and it's still broken...gotta fix that someday). I had a Heathkit DX-100 transmitter, which covered 160 meters. So I took an old tube type car radio, which in those days used a 262 KHz i-f and permeability tuning, and tweaked the inductors so it would tune the 160-meter band. I acquired a 262 KHz crystal and built an oscillator that I just let leak into the receiver for a bfo so I could copy CW.

My bedroom (shack) had steel casement windows and I had removed a pane and replaced it with a sheet of aluminum (no access to plastic in those days or coax, I was poor) with some ceramic feed thru insulators. I ran a single wire from the rig to near the top of a Eucalyptus tree (talk about dying for an antenna). I don't remember the length, maybe 100 feet, or the ground system; a single rod I think.

My first and only contact with that setup was DX; a VE7. The logs for those days are long gone so he's not in the current computer log. But if he was I would have a grand total of five countries worked on 160; about one every ten years [g].

What theory is it which says those antennas won't "work", given that your criterion for "working" is making contacts? I've made contacts on a light bulb, worked Alaska from a Colorado basement on 20 meters with 50 watts of SSB using a dipole(*) draped around the room with no part higher than ground level, worked New Hebrides on 40 meter CW running 1.5 watts to a bent attic dipole(**) 16 feet off the ground, and JA running 8 watts on 40 meter CW with a base loaded CB whip bumper mounted on a VW. These aren't exceptional -- every ham who's operated for some time has a handful of similar stories. All those antennas "worked". Any theory which declares they can't is wrong, and should be discarded. No theory I know says they can't.

(*) The feedline was 72 ohm twinlead, with one conductor stuck into the rig's SO-239 center pin and the other clipped onto the rig's chassis.
(**) Coax fed, no balun.

The only difference in the Texas A&M custom edition of
"University Physics" and the other editions is the big
maroon 'T' on the cover. Hint: Bad-mouthing Texas A&M
is probably a negative return on investment for you.
There's a good chance that one of your superior officers
in the military graduated from Texas A&M.

General Patton once remarked something to the effect:
Give me a bunch of West Point officers and I will win
a battle. Give me a few Texas A&M officers and I will
win the war (actual quote although not verbatim).

The only difference in the Texas A&M custom edition of
"University Physics" and the other editions is the big
maroon 'T' on the cover. Hint: Bad-mouthing Texas A&M
is probably a negative return on investment for you.
There's a good chance that one of your superior officers
in the military graduated from Texas A&M.

General Patton once remarked something to the effect:
Give me a bunch of West Point officers and I will win
a battle. Give me a few Texas A&M officers and I will
win the war (actual quote although not verbatim).

I need to come up with a dummy load for a 250+ watt xmitter.

IF I take two 100 watt wire wound resistors in parallel (for 50 ohms)
and put them in a can full of silicone oil and feed it though an L-Match
should it work?

Warmest regards,
John

Thanks for the help, Wes. I will be looking for that additional
thread. One of these days I'll get rich and famous and I can budget
the cost of EZNEC and get the full copy. 20 elements is just not
quite what I need for an antenna I am toying with in my mind.

BTW, how closely does the program get the measurements for antennas?
If I plot a dipole and EZNEC says the length should be 45 feet, will I
need to trim the antenna to a different length or will it be within an
inch or two?

>> just modeled one using the following stats:.....

Buck,
I ran EZNEC on your antenna, and the 1/4 wave section works like a charm. However it does not do anything to bring down the frequency of the 3/2 mode. You need to use another TV antenna trick. On a VHF antenna, elements that are resonant on CH5 and CH6 do no good in the 3/2 mode because they are resonant above CH13. What is done is this: you put a CAPACITOR in the element, like a loading coil would be. This forces you to make the element longer to work on the fundamental. The capacitor has less effect on the 3X frequency; So, you can actually have the 3X resonance be less than 3 times the 1X resonance.

Here is what I got:

Length +/- 34.5 feet
1/4 Wave section of 75 Ohm coax.
100 PF capacitor in each half of the dipole, about 5% in from each end.
SWR=1.5 at 7.0 MHz (50 Ohm)
SWR=1.1 at 21.2 MHz (50 Ohm)

I took a guess at the 100 PF number, and the capacitor placement; so, you can optimize it. Note that the further you move the capacitors from the ends of the antenna, the more effect they will have on the fundamental.

No we are saying the same thing two different ways. Let's first talk about the matching section. For example a G5RV may be modified by adjusting the feedline length from about 22 to 38 feet. From the end of the matching section you can run any practical length of coax.

If you had the top of your G5RV mounted at 100 feet, those length might not be practical. Adding an additional 1/2 wave length, or multiple thereof would allow the mechanism that switches in lengths of matching sections to be at ground level.

For example my 132 foot dipole uses 90 feet of fixed 450 ohm ladderline to the relay box. It is matched at 4035 and I then add sections to lower the frequency. 3.5 MHz requires an additional 39 feet.

On 7.3 the first Imax point is at 29.5 feet and adding an additional 1/2 wave brings us to 90.3 feet. We could just as easily used 151, 211, 272, 333 etc. Feet.

Where is the matching section? The first or the last 29.5 feet on the 90.3 feet? I think you could say that the first section matches the antenna impendence to somewhere around 50 Ohms and the 1/2 wave simply repeats it. Or you could say the first 1/2 wave section repeats the antenna impendence and the last 23 feet matches it. Potato, Patata, they both make the same fries.

about a decade back, I used to know an antenna engineer at Solarcon. He detailed to me the schematic for the antron (I wanted to use a similar setup for ham radio). The circuit is fairly simple and designed mostly for lightning protection..... :)

meanwhile, I use the homebuilt version running here at home on the 2 meter band (and it works nicely).

A little mea culpa. The above sequence fails to identify the
segmentation error in this model. I'm so used to using Multinec to
interface to EZNEC that I forgot that when using EZNEC directly this
error isn't trapped.

EZNEC's automatic segmentation check doesn't run when changing wire
lengths. It will allow the change that I made that results in too few
segments in the new length. The minimum number should be 13, with
more the merrier. With this simple structure, however, the error is
small and the other results are generally acceptable.

Exactly correct, actually you can replace it with 1/2 electrical wave length
of anything including lampcord. That being said you should not use lamp cord
before someone has a cow.

> less loss?)

No coax won't make a better match, a match is a match. The loss is lower on
the ladder line. The use of ladder line for a dipole designed for and used
on a single band probably doesent make a lot of sense. If you want to run an
80 meter dipole on all bands it is a must (sans a tuner). Look at it this
way 450 Ohms divided by 50 Ohms = 9 an 18:1 SWR at 450 ohms is only 2:1 at
50 ohms.

A waveguide can be considered a very wide bandpass filter. Any frequency coupled to the waveguide, within its pass-band, will appear at the output of the waveguide. There will be no spurious signals attributed to the waveguide. As mentioned previously; measurements I have made on microwave oven magnetrons indicate an extremely wideband, highly unstable signal, covering hundreds of MHz either side of the nominal 2.45 GHz. The potential for interference to other services, particularly the 2.4 GHz ISM band, and to a lesser extent, the 1.9 GHz cell frequencies, is fairly high. It is doubtful that any significant energy will be present at 800 MHz.

The relative spectral purity of the magnetron measured in http://www-personal.engin.umich.edu/~mcjz/papers/neculaes_tps04.pdf probably used a laboratory grade 4kV power supply. Note, however, that significant 120 MHz sidebands (and harmonics) are present.

I've checked this out, and one element IS 50 Ohms! (Or so it was for
the one I bought for $5 at the thrift store to investigate just this
application.) It worked better for AC/DC than RF.

How is it possible to decide whether or not a choke or balun is
needed, and where to locate it, unless the magnitude of what one MIGHT
wish to prevent is known.

I don't know about wattage, but measuring the
damage that a lack of decoupling does to the antenna
is easy to measure. Quite simple. Try each way,
and note the difference on a stable signal. The ringo
ranger without the lower section lost 3-4 S units
worth of performance in my case, using my line length.
Ditto for any other antenna. I found the decoupling of
simple 1/4 GP's can be improved also. Many, "including me"
often state that once a GP is at say 1/2 wave high, that only
3-4 radials are needed. As far as ground losses, this is true.
But the decoupling from the line can be further improved by
adding even more radials. Going from 4 radials to 8 usually
makes a noticable difference on a receiver...I consider a
receiver as just an poorly calibrated voltage meter in this
case. It's plenty good enough for A/B comparisons.
At HF, I don't worry about feedline radiation too awful much.
If I'm not torching my lips, wanking out my keyer, or causing light
bulbs to flicker in time to my CW or voice, I'm a happy camper.
Not so on VHF/UHF....I consider it critical if you want the best
performance. And....All this was tested in the real world by yours
truly...Over 20 years ago...I've had plenty of time to change my
stance...But I haven't...MK

For some dumb reason, I prefer to have a 'switch and transmit'
operation. On the CHN, I have a dedicated antenna matched
specifically for the 20 meter net frequency. Right now I use the
tuner on the 40 meter net so I just switch between 40 and 20 meters.
I will eventually build a 40 meter dipole with the 20 hung under it so
I don't even have to switch when I change bands.

As a novice I used a 40 meter dipole that matched perfectly on 15
meters. I just modeled that antenna to see how it turned out on the
rig. This is how I came to see that one impedance matched both bands
perfectly. (perfectly being defined as low SWR across the desired
portion of the band.)

All,
I am trying to use a wheatstone capacitance bridge to measure a very special capacitor that will change value in some frequency. To be precise, the gap between the capacitor plates will shake back and forth in a known frequency. I need some knowledge about the noise and sample rate of the capicitance bridge, so that I know I got a good data. Any idea about what reference book I should read. Thank you.

Hi Herman

You working with Phonon Polaritons?

A Wheatstone Bridge is not the best capacitance measuring bridge,
however, you may not have that option. A bridge of any sort is not
sample rate limited, the detector (or indirectly the method of
excitation) is. By and large, a bridge is a linear device and if you
want to use it as a demodulator, then you want to run the source
frequency of the excitation at least ten times faster. Nyquist would
demand at least twice, but that is not very useful to run at the
ragged edge if you want "good data."

Depending upon this excitation frequency, the utility of the common
Wheatstone configuration may degrade. It all depends on what you
consider to be accuracy.

Conect your special cap into an oscillator circuit and measure frequency change. A wheatstone bridge will have to be rebalanced with each change in capacitance.

I am assuming that your "special cap" will be moving a bit faster than you can balance; specifically since you mentioned frequency.

Once frequency is measured, you can calculate the capacitance. What is the range of your cap?

I sure encourage Wes and anyone else to post his experience with agreement or disagreement between modeling and measurement. But I've gotten a pretty good overview from the comments I've gotten in 15 years of selling EZNEC and its predecessor. These include reports from a spectrum of users ranging from amateurs who've measured what they can with the tools they have available, to professional users who have exceptionally good measurement equipment and access to high quality test ranges.

With quite a handful of caveats, below, the program gives very accurate results(*). Here are the caveats.

First, the antenna has to be just like the model. By "just like", I mean that anything materially affecting the antenna has to be in the model. Radiating feedlines are one of the most common elements overlooked by amateurs. I've also seen cases where the test meter itself is large and close enough to the antenna to change its impedance very significantly, and correspondence wasn't achieved until the meter was added to the model. Also, most people don't appreciate how much effect another antenna (or other resonant conductor) can have, even when surprisingly far away.

Next are a handful of modeling traps. These include but aren't limited to making sure the model is within modeling guidelines (segmentation, choice of ground type, etc.), that the NEC engine isn't having any particular difficulty (average gain close to 1), and the model doesn't contain any features which are known to cause an error (e.g., connected wires of different diameters, particularly in a parsitic element). Serious geometry errors such as connecting a wire end to a segment midpoint on another wire appeared quite frequently in files sent to me by users, which prompted me to expend the considerable effort to develop a comprehensive geometry check for the EZNEC v. 4.0 release. But many

errors can still be made. It takes a fair amount of care, knowledge, and experience to gain a high degree of confidence that all these conditions are met.

Then, even when the model is correct, most people don't know just how difficult it is to make good measurements. Measurements made through feedline are subject to a host of errors including failure to account for the effect of even a small amount of loss, and line impedance that's different from its specification -- a very common situation. Measurements made without feedline often suffer from the effects of common mode current and the close proximity of the person making the measurements. And so forth.

All that being said, it's really not hard to make a very decent model of a simple antenna -- or even a fairly complex one. But there are too many things I can't know about your modeling ability, how well you've suppressed feedline current in the real antenna, and how you'll be deciding that the antenna "works" to know if it'll come out within an inch or two.

Based on past experience, some number of the readers will interpret what I've written to mean that it's impossible to make a good model, or that modeling doesn't give accurate results. Neither is true at all. But a careless model and casual measurement probably won't match very well, either.

So my advice is to cut the antenna a bit long. Only after *you* have built and measured a few can you gain (or not gain) confidence in the ability of *your* models to match *your* measurements.

(*) I can't and don't take credit for the accuracy of the program. That's solely due to its NEC calculating engine which was developed by others. I will take blame for any EZNEC results which differ from those given by NEC. Those would be bugs, and I'd appreciate very much if anyone seeing a difference would contact me so I can track it down and fix it.

Quite often, one sees multiple turns of coax looped
under commercial elevated ground planes.

Thanks for the reply and comments.

I have been enjoying my time playing around with the program. I have notice that an antenna cut, trimmed and tuned at one location often has a different dip in another.

As for the program, I would like to order the full version of eznec, but I can't possibly budget that in right now. Is there a similar program available without the 20 segment limit? I am thinking I saw one many months ago when I first tried playing with this one.

Thanks,

According to an ARRL September, 1997, review of the Raibeam RB-206B (6 meters), it is a two-element HB9CV-type antenna. They go on to say

"In that design, two
dipole elements are driven out of phase
with respect to each other and closely
spaced."

The article footnote says

"For a description of the HB9CV mini-beam,
see the RSGB VHF UHF Manual (4th edition),
G. R. Jessop, G6JP, ed, pp 8.30 and
8.31."

Cheers,
John

Roy mentioned this patent a few years ago. I was fascinated and finally found it on the Patent Office web site. (Not a trivial task for someone who has never dealt with the patent office, but it may be easier now.)
It should be required reading for anyone who thinks Big Brother Knows Best. I assume it was submitted as a joke, or perhaps as a test. It certainly demonstrates that the patent process has become a joke, but anyone exposed to software patents knows this already.

When it comes to measurements, most amateurs and very many
professionals suffer from delusions of accuracy.

Making measurements is an ART rather than an engineering discipline.

ALL measurements are subject to error. Errors are distributed in
magnitude between trivial and catastrophic. Much of the art lies in
assessment of the magnitude of error and depends on the
measurement-makers' judgement and experience. Indeed, honesty is a
factor.

To gain support for the validity of a measurement result by stating
the manufacturer's name and serial number of the instrument used
doesn't carry much weight since accuracy depends on the person who
made the measurement and many other just as important factors. People
can't be avoided.

Something similar applies to numerical computer programs. The
reliability of a computer program depends on the programmer's
knowledge of the matter in hand and has nothing to do with the machine
it is running on. Far too much faith is placed on computed results
merely because they are computed.

Very little extra knowledge is gained by comparing a pair of computed
and measured results because there is no means of knowing how and from
where the inevitable difference arises.

Reliabilty and confidence of both programs and measurements require
time in which to accumulate. Mean time between estimated errors?

I was taught to record ID information of all the tools and instruments used, but I always took that to mean that it was to keep track of what things to check if anomolies cropped up.

Having said that, if someone gives me a 5-digit voltage reading taken by a 3-1/2 digit Rat Shack meter I'll believe it much less that if the reading is taken by a recently calibrated name-brand 5-digit meter (and I won't believe it much at any rate -- 5-digit voltage measurements have _lots_ of embedded voodoo).

Source record: 74955

At what frequency do you expect the plates to move? Is the motion a result of external forces, or of electrostatic forces caused by charge on the plates of the capacitor? What is the capacitance? Is the Q reasonably high? Is the leakage resistance very high? Answers to those questions may influence how you make the measurement.

I think Fred's idea of including the capacitor as a frequency control element in an oscillator is a good one. You can feed the oscillator output to an FM demodulator, or perhaps even use counting techniques to monitor the period of the waveform generated. It's possible to digitally demodulate quite accurately.

Another idea: use the capacitance like a capacitor microphone. That is, if the capacitance has very good insulation resistance, put a charge on it, and note that i=C*dv/dt+v*dC/dt; if i=0 (or very nearly so), then dv/dt= -(v/C)*dC/dt. (Alternatively, q=C*V.) If the frequency is high compared with 1/(R*C), where C is the nominal capacitance and R is the net leakage resistance, then i is practically zero. Research capacitor microphone circuits for further ideas.

Normally a bridge with a capacitor in one arm is not called a Wheatstone bridge...there are many different capacitor bridge circuits. See, for example, "Reference Data for Engineers" pub. by H. Sams for a chapter on bridge circuits and measurements.

If these ideas are not enough for you, do a search of journals. I'd especially recommend "Review of Scientific Instruments," which over the years has published myriad ways of measuring about any physical quantity you can think of. And if you come up with a new way, consider submitting it to them.

Cheers,
Tom

Aggie and a West point grad are dining together. The Aggie opines that his table mate must have attended West Point. "Why, yes I did, how did you know?" .

The Aggie replied "Your impeccable table manners, your manner of dress, and refinement of speech".

The West point grad then states "I see your an Aggie".

The Aggie puffs up with pride and expecting like accolades asks "How did you know?"

"I saw your ring while you were picking your nose during dessert"

Not sure how the magnetron would respond to a ramp, but at some amplitude the magnetron would cease oscillations. The fact is that the harmonic decay of a sawtooth waveform is slightly higher than a rectangular pulse. A worst case analysis would involve a rectangular pulse with a finite rise/fall time. If for example the magnetron were pulsed with a square wave, 50% duty cycle, at 1 MHz, with a rise time of 10nS, the 1,600 th harmonic (i.e. lower sideband at 800 MHz) amplitude is about -50 dBC. This result is obtained from the solution of the products of two Sa(x) functions involving the rise time, period, and pulse width of a symmetrical trapezoidal waveform. If you have a burning desire to know, I can vary the parameters of rise time, pulse width, etc. to see how the spectral shape changes.

These sidebands, in the vicinity of 800 MHz, are therfore of significant amplitude. I am, however, fairly certain that 800 MHz is below the waveguide cut-off frequency. I will try and measure the dimensions of a typical oven waveguide to determine its cut-off frequency. The other factor is the Q of the magnetron cavities how would this effect the banwidth of the spectrum? Since the magnetron is coupled to the waveguide from a probe in one of its cavities, I would think that the higher sidebands would be significantly reduced. Possibly you have made measurements on such a system.

The math, at least, does indicate the potential of building a very wide band jammer -- probably not a good idea!

73,

Frank

Thank you again for your replies.

I agree with your assessment that much of our (company's) internal (operational) systems may be considered "broken" by virtue of current circumstance. Unfortunately (or perhaps fortunately depending on ones point of view), I am not in a position to have any real effect in matters I am not paid to have an opinion on.

However, regarding the communications amongst the 40 or so busses I can have a positive effect on, there may be some positive contributions I can make. I have recently learned that our mechanic has been the one to install the radios, coax, and antennas all along.

The way the (broken) system apparently works:

Barn gets new bus in.
Manager asks for permission to buy new radio for new bus.
Uppon approval, manager orders new radio system (radio, coax, antenna, hardware, etc.), from local company.
Mechanic installs new radio into new bus.
Everyone hopes for the best.

In the course of conversation with our mechanic this morning on the matter, I learned that he has mounted a number of the antennas on a part of the bus that is fiberglass. I tried to explain a bit about ground-plane to him and the need for the antennas to be mounted on a metal part of the bus. I' am having him take one of the "worst" communicating busses and move the antenna to a metal part of the bus. I am also having him go through all the contacts and connections and cleaning them. I'll post what was done and what the results have been.

Thanks again for your help!

Mike

EZNEC-ARRL, a type of EZNEC v. 3.0, is included with the 20th Edition of the ARRL Antenna Book. It has a 500 segment limit when analyzing any of the several hundred EZNEC models included with the Antenna Book. You can modify any of those models and retain the 500 segment limit. However, if you save a modified model and open it again, the program will revert to the 20 segments of the demo version, since the saved file isn't one of the special ARRL files which relieve the segment limit. (Incidentally, all those several hundred models are recognized by standard EZNEC programs as ordinary EZNEC files, for those of you who have the standard program.)

There are several other programs available which have higher segment limits that are free. A web search and/or recommendations from other people should lead you to some of them. NEC-2 itself is free and available on the web, although you'll probably find it relatively difficult to use.

State of the State Secrets

Larry Franklin wanted to sway policy, not just spill intel.

by Justin Raimondo

The circumstances surrounding the arrest of Pentagon analyst Lawrence A. Franklin for passing classified information to two employees of the American Israel Public Affairs Committee (AIPAC) would make a good thriller. Acted out against a backdrop of war and terrorism, it's a cloak-and-dagger tale swathed in mystery, pregnant with political implications, and hinting at a subtext of hostility beneath the "special relationship" binding the U.S. to Israel. It has all the elements of good fiction-a strong plot, a fascinating set of characters, and a theme that will have the audience buzzing long after they leave the theater. Better yet, it looks like the dramatic climax will come in the form of a courtroom drama in a legal battle pitting the watchdogs of America's vital secrets against a shadowy fifth column.

For years the FBI's counterintelligence unit has been tracking a major espionage cell operating on behalf of Israel. Franklin stumbled into it one summer day in 2003, when he showed up at Tivoli restaurant outside Washington and met with two AIPAC officials-Steve Rosen, AIPAC's longtime foreign-policy director, and Keith Weissman, AIPAC's top Iran specialist. Franklin, described by his colleagues as a naïve ideologue who, as Ha'aretz put it, "believes wholeheartedly in the neo-conservative approach," revealed classified information about possible Iranian-sponsored attacks on U.S. forces in Iraq. Franklin was apparently worried that U.S. policymakers were insufficiently alarmed over the alleged Iranian threat to our interests in Iraq and was looking to enlist AIPAC-and the Israeli government-in pressuring policymakers to take a harder line on Tehran.

What he didn't know, as he spilled U.S. secrets, was that the FBI was recording his every word. It would be a while before he found out. Until then, he was watched, his phone conversations were recorded, and agents observed him trying to pass classified documents to an individual already under surveillance. However, as Newsweek described it, the unidentified Israeli spy was "too smart" for that, and insisted Franklin relate the information verbally.

An analyst with the Defense Intelligence Agency, Franklin served in the Air Force Reserve and did several tours of duty attached to the U.S. embassy in Tel Aviv. As Iran desk officer with the Defense Undersecretary for Policy, Near East South Asia, Franklin later moved to Douglas Feith's Office of Special Plans (OSP), where he and his fellow neocons cooked the intelligence on Iraq according to Ahmad Chalabi's special recipe and then served it up piping hot to Dick Cheney's boys, who delivered it straight to the White House. As Seymour Hersh relates, they called themselves "the Cabal"-a bit of self-mockery that, in retrospect, seems all too descriptive. OSP functioned, in effect, as a parallel intelligence agency. Its mission was to bypass the CIA, the DIA, and the mainline intelligence community and give the War Party the answers they wanted. The cabalists did not limit their activities to writing up talking points, however, but also engaged in field operations that caught the attention of the State Department and the CIA.

In December 2001, Franklin, along with Harold Rhode, a Middle East expert and Franklin's colleague in Feith's policy shop, and neoconservative writer Michael Ledeen-at the time working for Feith as a consultant-met with the infamous Manucher Ghorbanifar, of Iran-Contra fame, and a group of Iranians, including a former high official of the Iranian Revolutionary Guard. Also in attendance: Nicolo Pollari, head of the Italian intelligence service, and Italian Defense Minister Antonio Martino. As writer Laura Rozen tells it, "Ghorbanifar told me he has had fifty meetings with Michael Ledeen since September 11th, and that he has given Ledeen '4,000 to 5,000 pages of sensitive documents' concerning Iran, Iraq and the Middle East, 'material no one else has received.'"

In trying to discover how Iran had gotten its hands on vital U.S. secrets, including information on how the U.S. was eavesdropping on the Iranian government's encrypted internal communications, the FBI must surely have taken some interest in these activities. Their chief suspect, after all, was Chalabi, whose Iraqi National Congress supplied much of the grist for the OSP's mill.

A raid on Chalabi's Baghdad headquarters brought the whole affair into the open, and the Chalabi investigation has reared its head again in the Franklin affair. The Washington Post reports that the initial stage of the inquiry into Chalabi's activities as a double agent "focused on the activities of a US military reservist who was serving at the US Embassy in Israel."

When the FBI confronted Franklin and searched his home and office-turning up 83 classified documents, spanning three decades-he agreed, at first, to help the investigation, presumably in return for a promise of leniency. By some accounts, notably those by pro-AIPAC writer Edwin Black, Franklin agreed to make a series of monitored phone calls to suspects in the investigation, including neoconservative supporters of Chalabi. They also supposedly planted information via Franklin that Israeli agents operating in the Kurdish

area of northern Iraq were in danger of assassination by Iranian agents. The Jewish Telegraphic Agency reports that Franklin met with Weissman on July 21, 2004 outside Nordstrom's at the Pentagon City mall in Arlington and warned him about Israel's Kurdish problem. Alarmed, Weissman and Rosen passed this on to AIPAC, which raised the matter in meetings with NSC official Eliot Abrams. They also called Naor Gilon, top political officer at the Israeli embassy. This was followed shortly afterward by the FBI's first raid on AIPAC's Washington headquarters. (They would return four months later.)

=========

take a break from the nefarious anti-American intrigues of AIPAC terrorizing American liberties and security and look at the new hi tech weapons ["non lethal"] that Israel bought from black ops DIA zionists in the Pentagon and will use this August against the hapless Palestinians ...

Israel May Use Sound Weapon on Settlers

ISRAEL TO USE HAARP and GWEN mode MICROWAVE NON LETHAL WEAPONS ON PALESTINIANS WHEN THEY CRACK DOWN ON THE WEST BANK AND GAZA STRIP THIS AUGUST ...

...in a pre-arranged ousting of the legal occupants of the area, the indigenous yet beleagured Palestinians, ... Sharon will say it is to protect the illegal Hassidic settlers pouring for decades into the region from Brooklyn and Montreal and the Crimea/Ukraine region....

By AMY TEIBEL
Associated Press Writer

June 10, 2005, 12:50 PM EDT

JERUSALEM -- Israel is considering using an unusual new weapon against unwanted settlers who resist this summer's Gaza Strip occupation -- a device that emits penetrating bursts of sound that leaves targets reeling with dizziness and nausea.

Security forces could employ the weapon to overcome resistance without resorting to force, their paramount aim. But experts warn that the effects of prolonged exposure are unknown.

The army employed the new device, which it dubbed "The Scream," at a recent violent demonstration by Palestinians and Jewish sympathizers against Israel's West Bank separation barrier.

Protesters covered their ears and grabbed their heads, overcome by dizziness and nausea, after the vehicle-mounted device began sending out bursts of audible, but not loud, sound at intervals of about 10 seconds. An Associated Press photographer at the scene said that even after he covered his ears, he continued to hear the sound ringing in his head.

A military official said the device emits a special frequency that targets the inner ear. Exposure for several minutes at close range could cause auditory damage, but the noise is too intolerable for people to remain in the area for that long, he said.

Another official, also speaking on condition of anonymity because of his sensitive position, said the device hasn't been tested on subjects for hours at a time, so he couldn't discuss effects from prolonged exposure.

He said there was no direct connection between the recent introduction of "The Scream" and the forcible removal of settlers who resist evacuation orders, which is to begin in mid-August. But he didn't rule out the possibility of using it to root out settlers if persuasion fails.

The other official said "The Scream" could be used if protesters march on Gaza settlements or take up military positions.

"The whole issue of non-lethal is viewed from a desire not to get into a situation where soldiers are in distress and the consequences would be harsher than expected," he explained.

He said the military is still evaluating the device's debut performance in the field.

John Pike, director of the GlobalSecurity.org think tank in Alexandria, Va., said he believed last Friday's demonstration was the first case of such technology making it out of the laboratory and into the field. He said the U.S. and possibly China and Russia are developing acoustic weapons.

"I'm not aware of any other agency that is actively using it at this point," Pike said.

The military offered few details on the device, but Pike said he assumed it worked on very low frequencies that set off resonance in the inner ear. He said he was unaware of potential damage besides possible hearing loss.

Though the military refused to comment, Pike said the device probably sends its sound waves out in a specific direction, protecting the soldiers behind it.

"Most governments don't face large-scale demonstrations with a potential for lethal violence," he said. "So I think I would look to Israeli security forces to be an innovator in the non-lethal arena, simply because of the unique challenges it faces in the crowd control arena."

The military officials said Israel is constantly trying to bring new non-lethal weapons into the field but wouldn't disclose details. Its current arsenal includes tear gas as well as rubber-coated steel bullets, which have caused dozens of Palestinian fatalities.

Critics say Israel, with all its military technology savvy, should have done more in the years since the first Palestinian uprising began in 1987 to develop non-lethal weapons for use against hostile Palestinian masses.

Troops often turn to live fire, sometimes against teenage Palestinian stone-throwers. Police, too, used deadly force in October 2000 to put down rioting by Israeli Arabs at the start of the second Palestinian uprising. Thirteen Israeli Arabs were killed in those riots, and a commission of inquiry found that police used excessive force.

Israel's B'Tselem human rights group says Israeli security officers don't come equipped to police protests. "Although they could have anticipated they would have to disperse crowds, they didn't equip themselves with non-lethal means," spokeswoman Sarit Michaeli said.

Weapons they do have, such as rubber-coated bullets, are misused -- fired, for example, at too close a range, Michaeli said. The rubber-coated bullets can be lethal from close range.

Pike said the reason there aren't more non-lethal weapons available worldwide is because it is difficult to achieve both safety and effectiveness.

"The number of things that are genuinely effective at crowd control and substantially less lethal than lethal weapons -- it's a pretty short list," he said.

Weapons like pepper gas wouldn't put off a determined crowd, Pike said. Something like sticky foam might keep people out of a building, "but if I'm talking about controlling a mob in a city square, it just doesn't enter into play," he said.

Israel's past efforts to develop non-lethal crowd dispersal weapons included a gravel-spewing machine introduced and quickly abandoned during the first Palestinian uprising.

====

... back to Larry Franklin and his merry men of Sion and Carlyle Group ...

====

Whoever leaked details of the case to CBS News, including Franklin's identity, nixed the FBI's efforts to trace the transfer of sensitive materials from the spy nest embedded in our government to Israeli officials. FBI officials were furious: the leaker had effectively sabotaged their investigation, at least for the moment. Franklin stopped co-operating with the authorities, dismissed his court-appointed lawyer, and hired the high-priced law firm of Plato Cacheris.

The recent kickstarting of the prosecution, however, has seen a sea change in AIPAC's defense strategy. Rosen and Weissman have been handed their walking papers, and AIPAC is backpedaling furiously on its previous statements denying any wrongdoing by its employees, although the group is still paying the duo's legal bills. JTA reports indicate they are both to be indicted shortly, and Rosen anticipates the trial may begin as early as January 2006. He has pledged to fight the charges.

When this case comes to trial, it won't be only three spies for Israel who stand accused: the whole nexus of organizations and interests that came together in the War Party will be put in the dock.

When Franklin walked in unexpectedly on that luncheon meeting, he stumbled onto one of the biggest, most far-reaching espionage investigations since the Cold War. The crime committed in this case involves not only the theft of vital U.S. secrets but a concerted effort to influence American foreign policy on behalf of a foreign power. This is indicated, for one example, by the FBI's recent interrogation of Uzi Arad, formerly director of research for the Mossad and now head of the Institute for Policy and Strategy at Israel's Herzliya Interdisciplinary Center. According to The Forward, the FBI wanted to know why he had sent Franklin a research paper by Eran Lerman on how to re-invigorate America's relationship with Israel. Lerman, a former IDF intelligence officer, is the executive director of the American Jewish Committee's office in Israel. They also asked Arad about two conversations he had with Franklin: one at the December 2004 Herzliya Conference, which Franklin attended, and the other in the Pentagon cafeteria.

The Lerman paper argues that the U.S.-Israeli "special relationship" has fallen into "maintenance mode" in recent times and that America's grand democratization project in the Middle East calls for what Lerman dubs "the Special Relations Initiative of 2005." Whether this more assertive policy includes such activities as spying is a matter for conjecture, but the FBI's interest in a top AJC official shows that the scandal is widening.

It is also embracing more than lobbying groups like AIPAC and the AJC. The affidavit supporting Franklin's arrest noted that Franklin may have disclosed classified information to reporters, and the New York Times reports that federal agents have begun questioning journalists who may have written articles based on Franklin's revelations-the Times puts the number so far at four, "among them at least one newspaper journalist and others whose work has been published on the Internet." The JTA has named the newspaper reporter: Glenn Kessler, the State Department correspondent for the Washington Post.

The FBI is said to have taped a July 21, 2004 conversation that Weissman and Rosen had with Kessler. According to the JTA report, they joked about "not getting in trouble" over the exchange of information. "At least we have no Official Secrets Act," said Rosen, referring to laws on the books in Britain and elsewhere

prohibiting receipt of classified information. The joke, however, is on them. If the prosecution proves that they knew they were passing on classified information, including to an official of a foreign nation, they could wind up in the next cell over from Jonathan Pollard.

AIPAC's defenders lamely claim "mishandling" classified information is not the same as espionage. Franklin is charged with violating Title 18, Section 793(d) of the Espionage Act, which makes it a crime to pass to unauthorized persons "information the possessor has reason to believe could be used to the injury of the United States or to the advantage of any foreign nation." But Rosen and Weissman, who handed over classified information to Gilon, could face charges under Section 794, which carries a punishment of either death or life imprisonment for the crime of communicating information relating to the national defense "to any foreign government." According to a report in the New York Sun, the charges are so classified that AIPAC lawyer, Nathan Lewis, was required to get a security clearance to hear them.

The mystery at the heart of this investigation is how and when it began. Warren Strobel of Knight Ridder reported in 2004 that the probe "has been going on for more than two years," and UPI's Richard Sale cites a "former senior U.S. government official" as saying, "In 2001, the FBI discovered new, 'massive' Israeli spying operations in the East Coast, including New York and New Jersey," and they began watching Gilon, who eventually led them to Franklin. The JTA dates the genesis of the inquiry more precisely: "information garnered during the investigation into alleged leaks from a Pentagon analyst to the two former AIPAC staffers suggests the FBI began probing AIPAC officials just before the Sept. 11, 2001, terrorist attacks."

Like a dorsal fin poking just above the water, the Franklin spy trial promises us a glimpse of a creature much larger than appears at first sight. Whether the trial will draw it up to the surface remains to be seen. In any case, the magnitude of the problem posed by the covert activities of our ally-heretofore ignored or covered up-is all too clear.

Justin Raimondo is editorial director of Antiwar.com.

> merely because they are computed.

Agreed. This makes it essential that computed results be compared with measured results, or results calculated by other established methods, to gain confidence that the computer calculations are valid.

> . . .
> Very little extra knowledge is gained by comparing a pair of computed
> and measured results because there is no means of knowing how and from
> where the inevitable difference arises.
> . . .

I've found that to be completely untrue. I've done a good deal of design work in the areas of very high speed time domain circuitry and microwave RF circuitry, where direct measurement of internal functioning is impossible. I and my colleagues used modeling extensively in the course of our design work. An essential part of the process is to periodically look at the overall performance of a real circuit and compare it to the model. The model was adjusted (by varying unknown values, by adding components previously thought insignificant, and so forth) until the model adequately matched the measured results. This does, of course, require confidence in the measured results, which is subject to a host of potential problems. But the important thing is that agreement between the model and measurement must be gained in order to have any confidence in the usefullness of the model. It's not only possible, but critical to know how and from where the differences arise.

It sounds like you're saying that when presented with computed results we have no recourse but to put faith in the programmer. That's not at all so. We have to test the results against measurements or other calculations and resolve the differences before we can put much faith in any model or program.

With the rest, I agree.

Mike -

VERY USEFUL INFORMATION.

Yes, fiberglass is worthless for the required ground plane of a 1/4 wave UHF
antenna - and requires additional materials.
PCTEL based in the Chicago area is a major antenna mfg. and suppliers (e.g.
MAXRAD, Antenna Specialists).

They have 2 suitable products specifically made for fiberglass body vehicles and antenna mounting (Page 44 of their catalog)
http://www.antenna.com/lm_cat/pdf/lmr_catalog.pdf
Ground Plane Kit Model K-67

Ground plane kit for fiberglass-bodied vehicles. Complete with instructions and sufficient adhesive backed foil for one low-band/high-band or six UHF ground planes (3 inches x 44 ft). Includes metal clips for circuit continuity.

Ground Plane Disk Model K-332

Provides ground plane for fiberglass-bodied vehicles.

THIS NEEDS TO BE ADDED TO THE "BILL of MATERIALS that you are ordering from the "local company" supplying the radio and antenna materials

One other point Mike.

After this mechanic installs the COAX and ANTENNA - he can use his VOM to
assure that the center conductor and shield are NOT shorted
(unless you are using a loading coil or other special purpose antenna).
Every mechanic should be very familiar with this test from vehicle
electrical systems.

When people try to say you are talking garbage it sparks my curiosity, and have to see for myself. I should have realized that Sa(x) almost goes on forever. Even at 100 GHz from the carrier the sidebands are about -85 dBc. Other factors will probably suppress these very high order sidebands, but still interesting to crunch numbers. Now I have an overwhelming desire to build a -4000 V pulse generator, just to see how close it comes to theory.

73,

Frank

> All the best designs include it.
>
Let's see now. You say my proposition that an effect too small
to measure doesn't matter is "Total BS in most cases." Then
you give an "example" where the effect can not only be measured,
but the measured difference is very large "3-4 s unit(s)."

This strongly suggests that you did not understand the original
premise of "effects too small to measure." So let's try another
example, one far removed from antennas.

Let's say that ONE dust mite of 1,489,362 on your body at a
certain time decides to jump off while you're standing on the
bathroom scale--and that this event does not register on the scale.

I would say this too-small-to-measure event does not matter in
the real world. And even if you found a super laboratory scale
that actually could measure the mite departing, I would STILL
say the event does not matter. Your mileage may vary, of course.

Over in a digital camera forum I frequent, they have coined a
term to describe camera geeks who obsess about tiny differences
in camera system performance that have no practical significance
in real-world picture taking. The term is "measurebator."

Perhaps the term would also be useful in this NG. But we'll
probably have to add a new one of our own for the guys who
think modeling trumps practice. I suggest "modelbator."

Last but not least, if someone posts valid data showing that the
performance of an OSJ J-pole can be measurably, repeatably,

and significantly improved by a decoupling device, I'll be grateful
to him/her! And if the decoupling device is practical and affordable,
I'll want to know where to buy one, or how to build one.

Live long and prosper...

> (snip)
>
> > You are
> > starting to attract imitators.

1252. EZNEC ARRL and EZNEC 4 Demo: Setting default folders

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-15 19:54:57 UTC
From: Buck <iam@this.site>
Message-ID: <5m11b1lrjaeh2gc40va0fohcqjk9in26tb@4ax.com>
Source record: 74967

I completely uninstalled and reinstalled eznec 4 demo and the ARRL
version (3). I reinstalled them, ARRL version first and then demo 4.

I took the time to move my data folders to a separate drive and to set
the folder settings on the programs to point to those folders.
However, when I start back up, the program goes back to the default
and I have to manually redirect it.

I looked in the ini file but there was nothing there.

Any way to correct this?

Thanks, I reinstalled it. I had to uninstall everything and then
install ARRL first before it would work. Now, however, I have a
problem placing the folders where I want them. Is there a way to do
this?

I just finished experimenting with the ARRL version. I was able to
modify any file as long as I don't save or quit, i can get about as
elaborate as I want by hand entering all the data.

Frank:

Lol, it is catching huh?

Almost without doubt, what was tearing up my am radio was the signal being fed on the B+ rail (~1Mhz run by a "chopped" supply--and most likely leaking some signal onto the house mains--I am guilty of not making those suspicions clear)... however, their intent was to jam wireless wans/lans--from what I heard--they were/are more than successful...

I know there was great experimentation here in trying to get a microwave magnetron "rock stable"--when that failed it lead to the "other" experimentation...

Just in case there is something to this--be careful when and where you operate it...I think it just might surprise you...

Warmest regards,
John

1257. Yagi for 448or so mhz

Newsgroup: rec.radio.amateur.antenna
Date: 2005-06-15 21:43:13 UTC
From: Moto579 <ryanmeg@adelphia.net>
Message-ID: <1cCdnRPTa-RuPS3fRVn-vw@adelphia.com>
Source record: 74974

I would like to build a yagi for 448 mhz rangr for home use I have a 12 foot 1x1" piece of cedar and some 10 gauge copper wire It measures 0.15625" I think it is 10 gauge. Am I wasting my time? Also how do I use 75 ohm line as a feed line? All the plans I have found are for 50 ohm feedlines. It is all I have for wire and living out in the boonies it is difficult to travel to pick up some 50 ohm.

I'm on a budget / disabled and would appreciate any help/ knowledge/links/donations on this.
I own the ARRL Antenna book 20th edition and find it to be a bit overwhelming so far.

Cheers,
Ryan

The police who brought charges obviously thought he was guilty and
took precautions by locking OJ away, but legally, as far as the court
and the judge were concerned, he was presumed innocent and received
all of the judicial protections that that implies.

Hi Buck, Antennas have a 3-dimensional pattern. When you only want to see the Azimuth, you are looking at a 2D pattern, with a fixed elevation angle. The Azimuth plot must have an elevation angle to have meaning. The elevation angle you use depends on a number of factors. For instance, if you want to work dx, or want to hit a distant repeater, you want the most gain at low elevation angles. You want the Azimuth pattern to show the most gain at low elevation angles. I think 5-10 degrees qualifies as low angles.
EZNEC shows on the elevation plot the angle where the gain is maximum. It also has a 3D plot that really gives a good indication of where you are squirting the most signal.

How far away is the station you are trying to receive? What is it's elevation, and yours? What obstacles are between you and the station of interest? What are you feeding the antenna output to? What is the polarity of the signal from the distant station?

There are a gazillion yagi antenna designs. First let us know what you are trying to accomplish, that will determine the best design for your particular need.

You have the necessary stuff for a solution, once the needs are defined.

Thank you Gary, I have been looking at it a bit. I decided the best
way to get an accurate reading for the highest gain is to look at the
elevation and then set the azimuth elevation to the TOA.

Thank you,

Buck

Don't worry about the 50 or 75 ohm feedline. Just build the antenna and
feed it with what you have. If you build an antenna with a matching section
and have a good swr meter calibrated to 75 ohms you can match it.
If you don't have a meter you will have to take whatever you get.

Roy, put a new battery in your hearing aid. ;o)

The danger of putting much faith in the programmer is that he may belong to same set of old wives as the measurer and therefore make the same mistakes. Misconceptions are known to be popular. The two sets of incorrect results, measured and computed, then fatally agree with each other due to the correlation.

It's impossible for a program to be more reliable than the programmer. It can only be worse.

Your use of the word "before" implies a time span. The reliability of anything accumulates with experience, use and TIME. (Don't anybody mention bath tubs).

Reliability is Quality vs Time.

And Quality, in engineering terms, is the degree of conformance to specified requirements. Or, in more worldly terms as may be applied to computer programs, the fitness for the intended purpose.

Thus we can say that the accuracy of Eznec, etc., as determined over a number of years, is highly fit for its intended purposes.

Click Help, then Contents. This opens the EZNEC manual. Click the Index tab (key icon), then type "folders" (without the quotation marks) into the text box, or scroll down until you see "Folders".

You'll find the answers to most of your questions in the manual.

But what you're probably really interested in is the gain in the angle you'll be using for communication. Who cares what the maximum gain of the antenna is if that gain only occurs in directions (azimuth or elevation) you're not using for communication?

First, decide what elevation angles will be used for communication. One way to find that is by using a propagation program like W6ELProp (which is free). Look at the gain at those angles with EZNEC. The elevation angle at which the gain is maximum is of very little practical use -- EZNEC reports it only because a lot of people wanted it (for reasons which remain mysterious to me).

Well, I wouldn't characterize all cops as brain dead, besides, I
believe it is the attorneys in the DA's office who actually bring
charges. And, yes, it is their job to promote the perceived guilt of
the defendant, but otherwise, you would not have a court case. Nor is
that the same as saying someone is perceived guilty until proven not
so. It is the DA's job to overcome a perceived, legal innocence, in
the courtroom, of the defendant.

I'm getting bored... back to SWR.

When the microwave oven is running it interferes with my 200 kHz (conducted over house wiring) intercom system (Rat Shack). I suspected that it was noise from the power supply, and not the actual magnetron. I am still inclined to believe that the selectivity of the magnetron cavities will limit the modulated spectrum, not to mention the waveguide cut-off frequency. If I get a chance I will look more carefully at the RF output on a spectrum analyzer.

As for magnetron frequency stability and phase noise performance, I remember COHO/STALO MTI RADAR, and thought that the magnetron was stabilized. This is not true, as explained in http://www.alphalpha.org/radar/coho_e.html

The only way I can conceive of stabilizing is by the use of a tunable magnetron and AFC system. Then there is also the possibility of injection locking.

Considering the materials you have to work with, do a Google search on
"quagi antenna". Simple to build and no matching problems.

And even if you found a super laboratory scale
that actually could measure the mite departing, I would STILL
say the event does not matter. Your mileage may vary, of course.

Yes it varies a good deal...I'm not willing to throw away 3-4 S units
worth of low angle gain in the case of the ringo ranger.
It would take many mites to make up the difference.
Of course, the degree would vary to each persons
feedline. I was using about 50 ft.

Last but not least, if someone posts valid data showing that the
performance of an OSJ J-pole can be measurably, repeatably,
and significantly improved by a decoupling device, I'll be grateful
to him/her!

I've tested it, but I didn't collect data, other than in my head.
But there is no doubt that adding decoupling would make
the performance the same for any user. This will not be the
case without it. All decoupling will do is make sure you
get the gain you are supposed to. It's not going to help an
antenna that has little common mode problem to begin
with.

I suppose Al would have to have a poll....If the owners were
interested in the test...I don't really like J poles that much,
so I know I'm not going to waste my time repeating something
I did 20 years ago...

And if the decoupling device is practical and affordable,
I'll want to know where to buy one, or how to build one.

I've already described one simple version...I've tested it,
and I know it works. There are many ways you can do it..

>program asks for an elevation angle. WHat angle should I use? I have
>been randomly using 5 or 10 deg.

Depends. If you want to see the whole picture, use a 3D plot.

You should know that you can grab this with the mouse and change the
angle of view. By turning on the "Highlights" you can get any cut you
want on the pattern. Experiment.

For a feature rich (and free) alternative that will give you these
plots in living color see:

http://www.si-list.org/swindex2.html#4nec2_

That said, and not taking anything away from Arie's masterful work, I
recommend that you stick with EZNEC until you are more skilled at
modeling.

Many thanks for your reply. As I said I have been on that site but
unfortunatly it dosn't show you <how> the wire is terminated at the
ends. Obviously the 239 end isn't a problem, that's terminated in the
usual way, the main problem is how is the wire removed from the other
end is so that the whole assembly can be slid out and removed. If I can
find out how to remove that wire end from the metal socket/ threaded
collar, then all remains is to slowly pull the wire down from the 239
end and Hey Presto, Bobs yer Uncle....
TIA Dave.

With only 4 elements as listed, the elements will take up only about 24", so if you cut the boom down to about 30" or so, you can drill 2 holes near the back end of the antenna for a U-Bolt to mount it on a pipe or whatever. This should be a pretty portable antenna. Feedline length is not important, so use what you have.

Considering a wire dipole (or inverted V) does bending the end of a leg back and wrapping it around itself electrically shorten the antenna or must it be cut in order to change the resonant frequency?

if it is insulated wire it must be cut, if its not then it doesn't. though
you will see some effect of folding it back even with insulated wire it
won't be the same as cutting the wire shorter.

Source record: 74855

Hi guys,

I started a topic regarding magloop antennas few weeks ago asking about ways to replace the ferite coupling method. Some hams, to whom I deeply thank, have replied to the topic and provided some valuable insights on the matter.

Since then I managed to "build" an acceptable antenna. The only problem with it is that it doesn't work. yet, that is. HI!

Here's what happens : the moment I plug it into the FT100 (both wires, not only the central conductor) I get silent background (low level noise) as if it had no antenna at all. An uneducated guess of mine would be that maybe the feeder shorts *before* the coupling loop.

Here's a link to a page describing the way I did it which contains a small picture gallery of various parts. http://benny.kappa.ro/antenna/

Perhaps someone could enlighten me by providing any debugging tips and tricks. The downside is that I don't really have any specialised testing rig. I only own a multimeter, the ft100, the mfj in the picture and a soldering iron :]

Thank you for your time,

73 de YO8SSW

That being the case, can I just keep folding back a 120 foot insulated wire dipole until it is say 5 or 6 foot long and it will still be resonant on the original frequency?

Source record: 74861

Reading the responses, some valid, some not*, I guess the best
thing to try is:

o illuminate a surplus TVRO 12 ft dish with the magnetron
- collect and focus side lobes
- 36+ dbi gain
o use a regulated power supply the decrease the bandwidth
o use some form of bandpass filtering such as cavity resonators
o point the thing at the moon and listen for echos
o experiment using it as a ground mapping radar

I vaguely recall seeing something in a late 80's (?) magazine, may
be 73 or CQ VHF, that built a digital data link from a pair of 2 mbit
PC network cards and a magnetron.

* FYI:
o GSM cell phone bands = 850/1900 MHz for the Americas,
900/1850 MHz outside the Americas, not 2.4 GHz.
o microwave ovens with the door closed already interfere with
most 2.4 GHz ISM band FCC Part 15 devices in close proximity

No one said it would be resonant on the SAME frequency, just that
there will be some effect. I have heard about an antenna design for a
shortened dipole using 3-conductor home electrical wire. At one end,
the green is connected to the cobra-head and the black and white wires
are soldered together. At the other end, the black is soldered to the
green. Viola -- a linear loaded dipole!

I haven't tried it, but if it works, you may very well get your
desired frequency with folded wire. I would strongly suspect it will
be a compromise antenna as opposed to one with a gain, though.

Wouldn't this 'gain' be useful in figuring out just where you could dump your maximum signal somewhere in the world? It might not be where you want, but at least you might have an idea of where you would stick a loud signal using max gain at some elevation angle? Or is this a totally useless idea? I don't pretend to know what I'm talking about here, but it seems logical that by using this type of data it would help you figure out where you were going to put in a stronger signal.

Shields up!

Spoken like a true naif.

I suggest that you would take the time to learn what causes common mode current to be present on coax transmission line - regardless of what kind of an antenna it is employed. (For openers I suggest you start here http://www.w2du.com/r2ch21.pdf)

Then, after getting a grasp on that aspect continue to learn how common mode current on the transmission line can effect the overall performance of an antenna's radiation pattern - especially with VHF & UHF antenna systems then you just might understand what people here are trying to tell you.

However, I doubt that you would do that as it would appear you've made up your mind and don't want to be confused with known facts.

>Still others can't seem to understand that effects too small
>to measure usually do not matter in the real world.

Others have measured this and reported it to you, but for some reason you chosen to discount anyone who can show that it disagrees with your "pet" theory. For me, I've place your theory along with the world is flat, the moon is made of green cheese, and Iraq has weapons of mass destruction .

But even for a skeptic, I would thing that the thought of coiling up a few turns of coax costs very little, definitely won't hurt, and can only help. Would be sufficient.
